TMD: THE GREAT CONTROVERSY

Daniel N. Jenkins, DDS, LVIF, CDE
You are also not a sales goal or market segment. You are a dentist. And we are The Dentists Insurance Company, TDIC, where business is about doing what’s best for you, our policyholders. Here, you receive the respect and care deserving of a member of your profession. You have access to an in-house claims team, razor-sharp legal team and a peer committee that reviews every case. Why go to such lengths? Because with us, protecting dentists is all that matters.

**Protecting dentists. It’s all we do.®**

About a year ago, a California dental school administrator predicted that the “small, single-practitioner family dental office” would soon be a thing of the past. Put aside the corporate practices and the potential large retail store shops. Since then, the consolidated all-dentistry-under-one-roof offices and dentist-owned-and-operated group practices have been popping up on my radar. They’re everywhere. And they’re multiplying. They’re burgeoning.

Health policy experts at the American Dental Association maintain that the dental economy is “in transition.” Of course, we can all acknowledge the burst of consumerism in our practices. Patients are increasingly developing a new mindset and approach to managing their health. I think it’s a good thing. Patients have a right to choose who provides their care and how, and they deserve to understand why the care is needed. Because we are a small office, we are flexible to such demands. We take our time. We discuss our findings and reasons for diagnoses with patients at great length. We have the luxury of ensuring that our patients see the same familiar practitioner at every appointment. You know what you’re going to get when you come to one of our single-practitioner offices. Sometimes a turnkey group of associates sees the patients, while the name-on-the-door owner dentist handles the marketing and business aspects of the offices. Yet, sometimes we get lucky. The owner dentist finds a good fit in an associate — someone who can manage a satellite office, provide quality care to patients and follow through on the brand that the name on the door is supposed to represent. And if we could bottle the good-fit associate formula, wouldn’t we all aspire to start our own group practice?

The ADA’s Health Policy Institute notes that dentists who are 65 years of age and older are choosing this group practice model, second only to those who are 35 years of age and younger. Larger practices buy mass supplies at a cheaper cost; thus, services can be provided at a lower cost to the office. And the patient can receive dental treatment at a lower cost as well. It may be cheaper or easier for the large group practice to provide its employee benefits and retirement plans. The economies of scale tilt the scale in favor of many dentists choosing to expand their single-practitioner practices into a larger corporation with more dentists, more patients and perhaps more revenue.

Our colleagues in medicine are facing the extinction of the single-practitioner offices at a much higher rate. Accenture recently reported “a significant drop in physicians who practice independently, from 57 percent in 2000 to 39 percent in 2012.” The overwhelming majority, almost 90 percent, reported the top grounds for this transition were business costs and expenses. As one physician

Ruchi K. Sahota, DDS, CDE
in Minnesota noted, “The only way to survive … is having big pockets behind you, and that’s joining a hospital or joining an insurance company.”

Another physician cited the economic barriers (especially compensation and reimbursement) in recruiting new brilliant physicians and retaining the super-star physicians who were proven valuable members of their medical team. Many articles blame these financial issues on the changes mandated by the Affordable Care Act, pointing to the increases for independent medical practice overheads and changes in the reimbursement system.

Yet studies show that the transition from a single-practitioner medical practice to a salaried employee of a hospital is not always positive. An article on forbes.com cites “ample evidence” that this transition actually decreases employees’ productivity.

Evidently, this is not medicine’s first day at this rodeo. The rapid and large-scale hospital acquisitions of medical practices happened in the 1990s. The Forbes article attests, “The hospitals and practice management companies that went on buying binges … mostly failed. The doctors unwound the relationships and went back to running their own offices.”

Many questions arise. How do we survive extinction? Since single-dentist offices make up a large portion of CDA membership, will organized dentistry take on the responsibility of preventing our extinction? In fact, it’s actually ironic. A Guardian article explains that larger animals “tend to suffer the most in mass extinctions because they usually have specialized … requirements. Plants are harder.” The article goes on to provide tips on surviving mass extinction, two of which can perhaps be applied to our single-practitioner dental offices: Be a generalist and be good at surviving stress. We must have an ability to provide diverse patients with a variety of services and “keep going through bad times or be able to move into a new environment and survive.” Though we may be smaller, we have large patient populations and know how to be efficient with our resources.

Only time will tell if the dental administrator was right about our extinction. Perhaps many of our practices will become like the ivory-billed woodpecker or the little dodo bird. Our cities and suburbs may be targeted by a slew of corporate and group practices trying to run us out of town. But from what I’m told, our profession has a history of resiliency. We are nimble. We adapt. We will determine how to make the most of our individuality and set ourselves apart from the dinosaurs (or the giant group practices). I have a feeling that we won’t just survive. We will figure out a way to thrive in what may be a different dental world in the coming years.

The Journal welcomes letters
We reserve the right to edit all communications. Letters should discuss an item published in the Journal within the past two months or matters of general interest to our readership. Letters must be no more than 500 words and cite no more than five references. No illustrations will be accepted. Letters should be submitted at editorialmanager.com/caldentassoc.

By sending the letter, the author certifies that neither the letter nor one with substantially similar content under the writer’s authorship has been published or is being considered for publication elsewhere, and the author acknowledges and agrees that the letter and all rights with regard to the letter become the property of CDA.

Reminder for Members to Create New Web User Account

In order to better serve members, CDA implemented a new association management software system that enables CDA to update and streamline processes. The new software system requires members to create a new user account, which allows access to Practice Support resources, e-learning courses, the CDA Store and online dues renewal on cda.org. Even if a member has an existing account, a new one must be created.

Go to cda.org/password and follow a few easy steps to create a new web user account.

If you have any questions, please contact CDA at 800.232.7645.
Whether you volunteer, join in a fun fundraising event or make a donation, it’s easy to get that warm, fuzzy feeling with the CDA Foundation. It feels good to return smiles to Californians in need.

Treat People Better™
The End of Ethics

When do dentists stop their ethical development? We have heard that perhaps dental school is the last chance. Some believe it is all over by junior high school because of family and cultural influences.

The answer, of course, is that dentists can stop ethical development any time they want. Arguably, a rare few become rigidly set in their ways at an early age. Perhaps they hide their primitive ethical code under some fancy lingo. It would be a complete disservice to the practicing community to say that the book is closed on ethical growth when professionals cross the stage at graduation.

The three main approaches to ethics in the Western tradition are all products of mature thinkers. Aristotle’s virtue ethics — which is close to what we now call professionalism — was actually set down by his illegitimate son, Nicomachus. Jeremy Bentham’s utilitarianism — the greatest good for the greatest number — was the labor of a lifetime. Immanuel Kant — who believed in the imperative of good intentions much like the Golden Rule — wrote his great work on ethics at age 61.

For many dentists, their most ethical years are still to come. This question has drawn the attention of researchers. In the book, Moral Development in the Professions, James Rest and colleagues conclude that individuals continue to mature ethically as long as they continue to learn generally. As the Greek playwright Aeschylus noted, “To learn is to be young, however old.” Dentists probably learn more after graduation than before. It is just the focus of learning that causes the concern. I regularly look at the C.E. offerings of the dental schools in California, state meetings and the big regional meetings such as Rocky Mountain and Chicago Midwinter. These provide a mirror of where the practitioners’ collective attention is focused. It is not on ethics.

There are advantages in clinging to the misconception that ethics is fixed before dental school. First, this would excuse the need for engagement. If the other person is beyond the age of ethical plasticity, why bother to have the conversations? Certainly, the other would be wasting his or her time talking with me, one might say, as my values were set at an early age. This is a silly view to take — unless one is in a position of power and afraid to talk about alternative views.

A second advantage would be shifting the burden of training, mentoring and collegial interaction to selection. Sometimes it is said that schools have let the profession down by admitting students who have “nontraditional” values. That is a self-sealing indictment. There are no tests for ethical development that are valid for dental school admissions.

The nub:

1. In the fine print of the contract for life, it clearly states that all of us are responsible for our own ethical development and that this clause cannot be canceled at any point during one’s life.
2. It also says we are responsible for the ethical development of our colleagues — throughout their careers.
3. Tomorrow, each of us could be more ethical.

David W. Chambers, EdM, MBA, PhD, is professor of dental education at the University of the Pacific, Arthur A. Dugoni School of Dentistry, San Francisco, and editor of the Journal of the American College of Dentists.
Gum Disease Bacteria Selectively Disarm Immune System

The human body is composed of roughly 10 times more bacterial cells than human cells. In healthy people, these bacteria are typically harmless. But, when disturbances knock these bacterial populations out of balance, illnesses can arise. Periodontitis, a severe form of gum disease, is one example.

In a new study, University of Pennsylvania researchers show that bacteria responsible for many cases of periodontitis cause this imbalance, known as dysbiosis, with a sophisticated, two-pronged manipulation of the human immune system. Their findings, reported in the journal *Cell Host & Microbe*, describe the mechanism, revealing that the periodontal bacterium *Porphyromonas gingivalis* acts on two molecular pathways to simultaneously block immune cells’ killing ability while preserving the cells’ ability to cause inflammation. The selective strategy protects “bystander” gum bacteria from immune system clearance, promoting dysbiosis and leading to the bone loss and inflammation that characterize periodontitis. At the same time, breakdown products produced by inflammation provide essential nutrients that “feed” the dysbiotic microbial community. The result is a vicious cycle in which inflammation and dysbiosis reinforce one another, exacerbating periodontitis.

In this study, the researchers wanted to more fully understand the molecules involved in the process by which *P. gingivalis* causes disease. “We asked the question, how could bacteria evade killing without shutting off inflammation, which they need to obtain their food,” said senior author George Hajishengallis, DDS, PhD.

The team focused on neutrophils, which shoulder the bulk of responsibility for responding to periodontal insults. Based on the findings of previous studies, they examined the role of two protein receptors: C5aR and Toll-like receptor-2, or TLR2.

Inoculating mice with *P. gingivalis*, they found that animals that lacked either of these receptors, as well as animals that were treated with drugs that blocked the receptors, had lower levels of bacteria than untreated, normal mice. Blocking either of the two receptors on human neutrophils in culture also significantly enhanced the cells’ ability to kill the bacteria. Microscopy revealed that *P. gingivalis* causes TLR2 and C5aR to physically connect.

For more information, see the complete study in the June 11, 2014, issue of *Cell Host & Microbe*.

Dog Breed May Unlock Discovery on Cleft Palates

*Nova Scotia Duck Tolling Retrievers* may hold the key to learning more about cleft palates, a birth defect that affects approximately one in 1,500 live births in the U.S.

Researchers at the University of California, Davis, School of Veterinary Medicine have discovered a genetic mutation that causes cleft palate in this dog breed.

The genome-wide study of *Nova Scotia Duck Tolling Retrievers*, published in the *PLOS Genetics* journal, found that the dogs that have the mutation also have a shortened lower jaw, similar to humans who have Pierre Robin sequence.

“This discovery provides novel insight into the genetic cause of a form of cleft palate through the use of a less conventional animal model,” said Professor Danika Bannasch, a veterinary geneticist who led the study. “It also demonstrates that dogs have multiple genetic causes of cleft palate that we anticipate will aid in the identification of additional candidate genes relevant to human cleft palate.”

This is the first dog model for the craniofacial defect. Cleft palate is not commonly understood, so this is could lead to a breakthrough in research for humans.

According to the Mayo Clinic, cleft lip and palate “occur when tissues in the baby’s face and mouth don’t form properly. Normally, the tissues that make up the lip and palate fuse together in the second and third months of pregnancy. But in babies with cleft lip and cleft palate, the fusion never takes place or occurs only partially, leaving an opening (cleft).”

The findings of the study can be found at plosgenetics.org/article/info%3Adoi%2F10.1371%2Fjournal.pgen.1004257.
Natural selection may have provided humans with their thick dental enamel, according to new research.

A study conducted at Duke University compared the human genome with five other primate species and found two segments of DNA that led to the conclusion.

The study included gorillas, chimpanzees, orangutans, gibbons, rhesus macaques and humans. With teeth built to crush tough foods, humans came out on top in terms of enamel thickness.

“We decided to look just at genes that have a known role in tooth development,” said Greg Wray, PhD, professor of biology at Duke. The team chose four genes, each of which codes for a protein involved in tooth formation (enamelysin, amelogenin, ameloblastin and enamelin), making the genes good candidates for evidence of positive selection, though not necessarily the only ones involved in tooth evolution.

The research team plugged the gene sequence for each species into a software program that identified the base pairs that had changed between species and the changes that had accumulated faster than would be expected.

They used the concept of genetic drift to reach this conclusion. Drift is a phenomenon in which changes to the DNA sequence accumulate at an expected rate. When changes add up faster than expected, it suggests to scientists that the affected genes are under positive selection — that they give organisms some kind of advantage.

The analysis confirmed that matrix metallopeptidase 20 (MMP20) shows the distinct signature of natural selection acting on tooth enamel thickness in humans. They also found another gene, called ENAM or enamelin, which is under positive selection.

Timothy Bromage, PhD, professor of biomaterials and biomimetics at New York University, said, “This study provides the important bridges between morphology, developmental processes, and their underlying genetic regulating mechanisms.”

The ultimate goal for the researchers is to create a roadmap for navigating the many ways natural selection is linked.

Humans’ Thick Enamel Tied to Natural Selection

Guided Bone Regeneration Treats Implant Lesions

Oral implant surgery is complex and not without complications, one of which is an implant periapical lesion (IPL). If the lesion site becomes infected, it can lead to an abnormal growth, persistent inflammation and tenderness. However, a procedure that allows complete bone regeneration at the implant-related lesion site shows promise in treating the resulting bone defect and infection.

In a Journal of Oral Implantology case study titled “Active implant periapical lesion: a case report treated via guided bone regeneration with a five-year clinical and radiographic follow-up,” surgeons reported using guided bone regeneration (GBR) principles to completely remove the lesion and any subsequent infection.

IPL is a rare disorder, affecting approximately 0.26 percent of the population receiving implants. There are varying reasons for its incidence, and it can sometimes be misdiagnosed or confused with retrograde peri-implantitis. The combination of antibiotics and GBR principles has been shown to be an effective treatment for IPL, keeping the implant intact, and creating a complete bone fill at the lesion site. This case study appears to be the first of its kind, so further research will be needed to confirm the findings.

The full article is available online at joionline.org/doi/full/10.1563/AAID-JOI-D-11-00214.
I just have a quick practice management question, but who can I ask that I trust?

CDA members have access to Practice Support Analysts who are experts in dental benefits, practice management, regulatory compliance and employment practices. Always just a phone call or email away, they have the advice, answers and the perspective you need to make sound decisions. So, put them on speed dial, save their email addresses and know that they’re here to help.

CDA Practice Support. It’s where smart dentists get smarter.

UB Receives $4 Million NIH Grant to Study Oral Health in Postmenopausal Women

University at Buffalo researchers have received an interdisciplinary bioinformatics grant of nearly $4 million from the National Institute of Dental and Craniofacial Research of the National Institutes of Health to conduct a prospective study of the oral microbiome and periodontitis in postmenopausal women.

The study will investigate a critical gap in the knowledge about the composition and role of the oral microbiome, composed of the bacteria found in mouths. It will consider, in particular, the microbiome of the subgingival area and especially between the gums and the basal part of the crowns of the teeth.

Researchers theorize that certain compositions of this diverse microbiome are associated with periodontal disease prevalence, severity and progression over time.

The study will involve investigators from the UB School of Medicine and Biomedical Sciences, School of Dental Medicine, School of Public Health and Health Professions, UB’s New York State Center for Excellence in Bioinformatics and Life Sciences and the new Genomic Medicine Network, which is co-led by UB and the New York Genome Center.

“Of our knowledge, there is no prospective epidemiologic study as large and rich with available data resources that can address the cutting-edge questions we propose here on the oral microbiome and its relationship to periodontitis in postmenopausal women,” said Jean Wactawski-Wende, PhD, a professor in the Department of Epidemiology and Environmental Health, UB School of Public Health and Health Professions, and director of the Women’s Health Initiative’s Buffalo Center. “We expect our results to lay the foundation for the study of the association of the oral microbiome to the development of other chronic diseases of aging.”

Researchers will use frozen subgingival plaque samples from that study collected at baseline and post-baseline at year five; data from standardized oral exams that will characterize the extent of subjects’ periodontal disease; and extensive information on personal factors (e.g., smoking, dietary intake, obesity, diabetes, hormone use) and overall health status.

These techniques involve Next Generation Sequencing (NGS) using culture-independent techniques to identify 16S rRNA genes and allow for a more complete and detailed characterization of the microbial composition and diversity of the human oral cavity, according to the researchers.

For more information, see the news release at buffalo.edu/news/releases/2014/06/016.html?shash=NXjglXcn.dpuf.

Not Enough Children Seeing Dentist by First Birthday

Children should visit a dentist by their first birthday, but according to a recent study conducted by a pediatrician and researcher at St. Michael’s Hospital in Toronto, that isn’t happening as often as it should.

Jonathon Maguire, MD, surveyed 2,505 Toronto children around the age of 4 over a two-year span. He found that 39 percent of the children had not yet seen a dentist.

The study revealed that never having been to a dentist was associated with younger age, lower family income, prolonged bottle use and higher daily intake of sweetened drinks such as juice. With each one-cup increase in the amount of sweetened drinks consumed daily, the odds of never having visited a dentist increased by 20 percent.

In addition, 24 percent of the children who had seen a dentist had at least one cavity, according to the study, which was published in the journal Pediatrics.

Among children who had been to a dentist, older age, lower family income and East Asian maternal ancestry were also associated with having one or more cavities.

For more information, see the study in the June 2014 issue of Pediatrics.

CDA’s tips for a healthy smile in young children include: brushing twice a day with fluoride toothpaste; visiting the dentist by age 1 or when the first teeth come in; asking the dentist about fluoride and sealants; visiting the dentist regularly (California law now requires kindergartners to have a dental check-up); choosing water instead of soda or other drinks that contain added sugar; limiting between-meal snacking, especially on sugary and sticky foods; and choosing gum or mints that contain xylitol.
Light Coaxes Stem Cells to Repair Teeth

A Harvard-led team is the first to demonstrate the ability to use low-power light to trigger stem cells inside the body to regenerate tissue, an advance they reported in Science Translational Medicine. The research, led by Wyss Institute Core Faculty member David Mooney, PhD, lays the foundation for a host of clinical applications in restorative dentistry and, more broadly, in regenerative medicine, such as wound healing, bone regeneration and more.

The team used a low-power laser to trigger human dental stem cells to form dentin, the hard tissue that is similar to bone and makes up the bulk of teeth. They also outlined the precise molecular mechanism involved and demonstrated its prowess using multiple laboratory and animal models.

A number of biologically active molecules, such as regulatory proteins called growth factors, can trigger stem cells to differentiate into different cell types. Current regeneration efforts require scientists to isolate stem cells from the body, manipulate them in a laboratory and return them to the body — efforts that face a host of regulatory and technical hurdles to their clinical translation. But Mooney's approach is different and, he hopes, easier to get into the hands of practicing clinicians.

"Our treatment modality does not introduce anything new to the body, and lasers are routinely used in medicine and dentistry, so the barriers to clinical translation are low," he said. "It would be a substantial advance in the field if we can regenerate teeth rather than replace them."

DAVID MOONEY, PhD

Oral Cancer-fighting Patch in the Works

The Ohio State University and the University of Michigan have signed an agreement with Ohio-based Venture Therapeutics Inc. to develop and commercialize a pharmaceutical technology targeted at the treatment of precancerous oral lesions. These lesions are currently managed by invasive surgery, and approximately a third recur after surgery.

Previously published data show that about 30 percent of the higher grade precancerous oral lesions progress to oral cancer, specifically oral squamous cell carcinoma. This type of cancer is particularly devastating to patients because treatment entails removal of facial and mouth structures essential for esthetics and function. The National Cancer Institute estimates that 42,440 Americans will be diagnosed with oral cancer and more than 8,390 oral cancer-related deaths will occur in 2014.

Precancerous oral lesions can be seen and touched by patients, and this easy access to the lesion allows the use of local delivery formulations in an oral patch to directly treat the disease without causing adverse side effects.

"This type of collaboration, involving multiple university partners with strong industry support, is increasingly essential to expedite the discovery, development and delivery of more targeted cancer therapies. There is no routine cancer, and today it takes the collective minds across disciplines, institutions and industry to move the field forward," said Michael Caligiuri, MD, director of The Ohio State University Comprehensive Cancer Center.

"Ultimately, these collaborations can be the catalyst for new, more effective cancer treatments, leading to better outcomes, faster responses, fewer side effects and more hope for cancer patients everywhere," Caligiuri said.
Nearly half of all adults in the U.S. suffer from periodontitis, and 8.5 percent have a severe form that can raise the risk of heart disease, diabetes, arthritis and pregnancy complications.

University of Pennsylvania researchers have been searching for ways to prevent, halt this mean and reverse periodontitis. In a report published in the *Journal of Immunology*, they describe a promising new target: a component of the immune system called complement. Treating monkeys with a complement inhibitor successfully prevented the inflammation and bone loss associated with periodontitis, making this a promising drug for treating humans with the disease.

Earlier work by the Penn team had shown that the periodontal bacterium *Porphyromonas gingivalis* can hamper the ability of immune cells to clear infection, allowing *P. gingivalis* and other bacteria to flourish and inflame the gum tissue.

The researchers wanted to find out which component of the complement system might be involved in contributing to and maintaining inflammation in the disease. Their experiments focused on the third component, C3, which occupies a central position in signaling cascades that trigger inflammation and activation of the innate immune system.

The team found that mice bred to lack C3 had much less bone loss and inflammation in their gums several weeks after being infected with *P. gingivalis* compared to normal mice. C3-deficient mice were also protected from periodontitis in two additional models of disease: one in which a silk thread is tied around a tooth, promoting the buildup of microbes, and one in which the disease occurs naturally in aging mice, mimicking how it develops in aging humans.

“Without the involvement of a different complement component, the C5a receptor, *P. gingivalis* can’t colonize the gums,” said George Hajishengallis, DDS, PhD, a professor in the School of Dental Medicine’s Department of Microbiology. “But without C3, the disease can’t be sustained over the long term.”

Building on this finding, the researchers tested a human drug that blocks C3 to see if they could reduce the signs of periodontal disease in monkeys, which, unlike mice, are responsive to the human drug. They found that a drug called Cp40, a C3 inhibitor that was developed for the treatment of the rare blood disease paroxysmal nocturnal hemoglobinuria (PNH) and ABO-incompatible kidney transplantation, reduced inflammation and significantly protected the monkeys from bone loss.

According to the researchers, this study represents the first time, to their knowledge, that anyone has demonstrated the involvement of complement in inflammatory bone loss in nonhuman primates, setting the stage for translation to human treatments.

The results, Hajishengallis said, “provide proof-of-concept that complement-targeted therapies can interfere with disease-promoting mechanisms.”

For more information, see the study in the *Journal of Immunology* published online first May 7, 2014.
This year, be inspired.

CDA Presents The Art and Science of Dentistry is one of the most anticipated dental conventions in the U.S., thanks in part to the dynamic exhibit hall. With new product launches and hundreds of exhibiting companies, this is the place to be inspired by the latest innovations in dentistry.

TMD: The Great Controversy

Daniel N. Jenkins, DDS, LVIF, CDE

Twenty-five hundred years ago, Hippocrates recorded in his sixth book of Epidemics his observation, which confirmed traditional thought of the time, that many people with severe headaches also had crooked teeth. Over the centuries, while the tooth-headache connection was accepted, there did not seem to be a consistently successful treatment. With the advent of pharmacological pain medications in the 20th century, head pain was treated by drugs, thus treating the symptoms and not the cause. Since the patient’s primary goal is pain relief, drug therapy was deemed a success by the patient — at least for a while.

Most dental students are taught a centric relation (CR) philosophy regarding TMD. While there are more than 25 accepted definitions of CR, the most common one taught in dental schools in the U.S. is that the proper position of the condyles of the mandible is in the uppermost and most posterior position in the glenoid fossa. (Thus, it fits into place like a puzzle piece.) Based on this CR position, a TMD patient in pain has often had teeth reconstructed to maintain CR. Keeping in mind that many people have achieved pain relief and function from this CR position, you might ask, “Why?” In fact, there are probably successful cases with every other CR position and TMD philosophy. Otherwise, why would dentists keep treating patients by using those approaches? (Although, at a recent TMD debate, one presenter admitted that she had TMD and has not been successful in curing it with her own philosophy.)

TMD pain is transmitted to the brain by nerves. Among the many TMD philosophies I have studied or reviewed, pain by nerve transmission is accepted. The controversy arises over what causes the pain and what is to be done about it. Relieving TMD pain is only a short-term goal; treating the cause to keep it from recurring is the long-term goal. I have relieved many TMD patients of their pain within a few minutes simply by having them close lightly on a cotton roll with their anterior teeth — but that is not a long-term solution.
Sixty-plus years ago, Bernard Jankelson, DDS, in search of relief for his wife’s MS symptoms, developed the neuromuscular philosophy of TMD treatment, which theorized that the pain transmitted via the nerves to the brain was caused by muscle strain. Prior to this, he practiced CR. The idea of muscle strain causing pain is not unusual in most TMD philosophies; the debate is about how to achieve it and whether it is possible to determine objectively when the muscles achieve calm.

In 1959, Laszlo Schwartz, DDS, published his biopsychosocial philosophy of TMD. This considers pain physiology with comorbidities elsewhere in the body and mind as well as life events that can elicit pain responses in the TMJ area. Charles Greene, DDS, an editorial board member of The Journal of the American Dental Association, wrote an editorial piece in the September 2010 issue under the auspices of the American Association of Dental Research, stating that the biopsychosocial philosophy was a “new guideline for care” for TMD. This caused a lot of controversy in the TMD world and a record number of letters to the editor of JADA, most in opposition of Dr. Greene’s piece.

This revival of the TMD controversy has stimulated study of the many TMD philosophies. Dentists who wish to study TMD are amazed at how many philosophies there are. Because most dentists were originally taught the upper-posterior CR position in school, which is now rarely taught, they will have to evaluate the many other methods or philosophies, meaning an in-depth examination and understanding of anatomy, physiology, physics, occlusion, psychology and social behaviors.

In this issue, four authors state their differing TMD philosophies. Each then reviews the other three authors’ statements of philosophy, so you can understand each one’s opinion, as a TMD expert, on what they feel are the differences among them. Following those reviews, the authors respond to the critiques of their individual philosophies. The difference between some authors may seem slight, but those differences are clearly important to them.

I was originally asked to gather authors from all the various philosophies, but due to the number of philosophies that exist, that was impossible. However, I did ask many leaders of TMD philosophies, organizations and institutes to participate in this unique issue. I even sent an invitation to Dr. Greene, the originator of our newest controversy, but he graciously declined to participate.

However, James Fricton, DDS, MS, from the dental school at the University of Minnesota, is capably representing the biopsychosocial philosophy. He is also well known in the oral facial pain area. Clifton Simmons III, DDS, practices TMD in Chattanooga, Tenn. Michael Gelb, DDS, MS, directs a TMD-sleep institute in New York City. TMD dentists will recognize the Gelb name from his father Harold Gelb, DDS. Prabu Raman, DDS, MICCMO, LVIM, FPFA, FACD, has conducted a practice limited to neuromuscular TMD for 20 years in Kansas City, Mo. While my relationship to Dr. Raman is the closest of the four authors, working with them for the last two years on this issue has given me a great respect and a bond with all of them that I will always value.

My hopes are that you will be stimulated to study TMD for yourself and decide on a treatment philosophy, whether it be one of the four presented here or another. Remember, none of us knows what we don’t know, and that is why we should all keep learning. I wish you success and peace.

Temporomandibular Disorders: A Human Systems Approach

James Fricton, DDS, MS

ABSTRACT The face and associated cranial, oral and dental structures are among the most complicated areas of the body, contributing to an array of common orofacial disorders that include temporomandibular disorders (TMD), orofacial pain disorders and orofacial sleep disorders. This paper presents a broad, inclusive approach to diagnosis and management of TMD that reflects both conceptual models of human systems in understanding chronic illnesses as well as systematic reviews of treatment for successful management.

AUTHOR

James Fricton, DDS, MS, has devoted his career to patient care and research in temporomandibular and orofacial pain disorders. He is a senior researcher at the HealthPartners Institute for Education and Research and treats patients at the Minnesota Head and Neck Pain Clinic in Minneapolis. He is professor emeritus in the Department of Diagnostic and Surgical Sciences in the School of Dentistry at the University of Minnesota. Dr. Fricton has published and lectured extensively, is the author of TMJ and Craniofacial Pain: Diagnosis and Management, Myofacial Pain and Fibromyalgia and Advances in Orofacial Pain and TMJ Disorders and is serving as president of the International Myofascial Society.

Conflict of Interest Disclosure: None reported.

The face and associated cranial, oral and dental structures are among the most complicated areas of the body, contributing to an array of orofacial disorders, including temporomandibular disorders (TMD), orofacial pain disorders, orofacial sleep disorders, oral lesions, dental disorders and oromotor disorders. Orofacial pain disorders are the most common of these problems and can cause symptoms of orofacial pain, jaw dysfunction and chronic head and neck pain, with a collective estimated prevalence of at least 20 percent of the general population (Table 1). To complicate matters, oral and craniofacial structures have close associations with the functions of eating, communicating, seeing and hearing, and they form the basis for appearance, self-esteem and personal expression and, thus, can deeply affect an individual’s psychological and functional status. A national poll found that adults working full time miss work because of head and face pain more often than for any other site of pain.

The high prevalence, personal impact and poor access to care for these problems have led to an expanded role for dentistry in providing solutions. However, because dentists focus most of their patient care on treatment of the dentition and related structures, it can be a challenge to understand the broader scope of diagnosis and management of these conditions. Treatment of TMD, like many pain conditions, is often singular and can vary according to the clinician’s favorite theory of etiology. Clinicians tend to see what they treat and treat what they see. Clinicians who see a stress etiology treat...
with stress management; surgeons who see a joint pathology treat with surgery; and dentists who see a dental etiology treat the teeth. As a result, treatment success is often compromised by limited approaches that address only part of the problem.

This paper summarizes a broader, more inclusive philosophy in diagnosing and managing TMD that reflects both new conceptual models in understanding chronic illnesses as well as systematic reviews of therapeutic strategies for successful management of TMD.

**Human Systems Theory: A Comprehensive Model for Understanding Chronic Illness**

Humans are complex, multidimensional and dynamic and live within an ever-changing physical and social environment. Yet our traditional biomedical model is based on a scientific paradigm that is unidimensional, reductionist and inflexible because it is based primarily on understanding the underlying pathophysiology. While distinct pathophysiological mechanisms occur in all chronic conditions, understanding the multitude of factors that play a role in the onset, perpetuation and progression of the illness is the key to successful management. Thus, traditional scientific protocols often fall short in providing an adequate framework for explaining, predicting and influencing chronic illness and its outcomes. Scientific and clinical communities have been searching for a more flexible, holistic and integrated model that describes the changes in human biology that can occur in response to the circumstances in our lives which contribute to the balance between health and illness.

Human systems theory (HST) provides this framework. As originally stated by Aristotle in 300 BC, “The whole is greater than the sum of its parts.” HST stems from research in general systems theory and originated in ecology out of the need to explain the interrelatedness of organisms in ecosystems. While conventional biological theories view the subject as a single entity, HST views a person as a whole in an interrelationship between the subparts of his or her life. These subparts are not static but rather are dynamic, evolving and interrelated processes. The practical application of HST to patient care requires that we understand basic HST principles as they apply to the development and alleviation of illness. These include:

- Seeing the whole patient through the eyes of the biopsychosocial medical model.
- Understanding recursive feedback cycles using cybernetics.
- Seeing the broad cumulative impact of small changes using chaos theory.
- Understanding the power of positive action through positive psychology and behavioral medicine to enhance health as part of the treatment of illness.

These concepts provide a new model for understanding TMD and its management that is well founded in theory and science. It is beyond the scope of this paper to present an in-depth discussion of each concept. However, for those interested in reading further, the concepts are presented in a more creative format than traditional academic texts — i.e., as a murder mystery novel — as well as part of a University of Minnesota massive open online course (MOOC) at coursera.org/course/chronicpain.

The biopsychosocial medical model was first proposed by Engel in 1977 and suggested that to understand health and illness, one needed to look at the whole person and not simply at physical pathophysiology. It recommended that we “see the big picture” of illness. Most studies of risk factors and protective factors suggest that each person has a unique set of interconnected factors that can either perpetuate or protect from an illness, including TMD. These contributing factors correspond to each realm of our lives, including the mind, body, emotions, spirituality, lifestyle, social relationships and the physical environment (Figure 1). By improving them, the strategies for management have greater success than the sum of any individual treatment directed at one realm.

Cybernetics, a concept defined in physics, was first applied to human systems by Bateson in 1978. It suggests that “what goes around comes around” and each element of a system generates a change, which causes feedback to the entire system. Positive feedback triggers a
continuation of the cycle, while negative feedback leads to its discontinuation. This is often referred to as a self-reflexive or “circular causation” relationship. Positive and negative feedback cycles play an important role in sustaining a person’s illness over time (FIGURE 2). Patients with an illness often fall into the recursive cycles that perpetuate the illness. Contributing factors to an illness, such as repetitive strain, depression or poor sleep, are elements that sustain the cycle.

Several types of change can influence these cycles (FIGURE 3). First-order change is based on “reinforcement” of existing elements that promote maintenance or escalation of the existing cycle and its related illness. A second-order change involves a “revelation” that makes a significant change from within the system through multimodal education, training and treatment that lead to a new state. Finally, a third-order change is based on “enlightenment,” which produces a change from outside to achieve a new level of existence distinctly different from the original structure. Second- or third-order changes are the basis for significant improvement of a condition to create a new paradigm for the health of the individual.

Small first-order compensatory changes made by a patient in response to TMD pain, such as reducing use of the jaw, taking an analgesic or other self care, can improve the illness if it is an acute self-limiting problem, at least in the short term. However, these compensatory changes may also allow a more complex illness to fall into a long-term chronic cycle (FIGURE 2). If a clinician can help a patient make higher order changes by understanding the multiple elements in the cycle and changing those keystone factors that perpetuate it, the illness may change more readily. Integrative care strategies that encourage second-order change within an existing cycle include splints, physical therapy and behavioral management of oral habits, sleep and muscle tension. This strategy works quite well for simple to moderate cases, but more complex patients may need a more robust intervention. In those cases, transformative care strategies encourage third-order changes that can lead to the most dramatic long-term results. Third-order change involves not only treatment of the TMD pain as noted, but also working with a team to identify all comorbid conditions and contributing factors and helping the patient make major changes to factors that may be perpetuating the long-term cycles. These changes could include managing a comorbid medical condition such as fibromyalgia, addressing stressful or abusive relationships and changing poor work situations. In this way, healthier, positive feedback cycles are set up that do not perpetuate the factors that drive the illness.

Chaos theory was first popularized by Lorenz (1963) in a paper on the theories of diverse weather patterns entitled “Does the Flap of a Butterfly’s Wings in Brazil Set off a Tornado in Texas?” He presented evidence that small differences in initial conditions of a system might yield widely diverging outcomes within dynamic systems. Chaos theory suggests that “it is the little things that matter...
the most.” When applied to health and disease, it suggests that multiple risk factors can each play a small role at early stages of a chronic illness. However, when these factors are combined, they will accelerate the condition dramatically.

As FIGURE 4 illustrates, an illness begins with initiating factors such as acute physical injury of the muscles and joints. In most cases, this pain is transient and resolves without complication or persistence. However, if a sufficient number of contributing factors are present, even though small, the balance can shift from healing of acute pain to delayed recovery and chronic pain (FIGURE 2). Various underlying neural mechanisms, such as peripheral and central sensitization and wind-up, play a role in this process that is difficult to predict. Likewise, the presence of protective factors and early intervention in multiple factors will have the greatest impact in resolving the condition.

Behavioral medicine, then, suggests that specific behavioral interventions such as exercise and oral habit reversal can help restore health and wellness. It complements theories on positive psychology that focus on building health, strength and positive virtues as much as on correcting illness, problems and vices. The Aristotelian idea that we are what we repeatedly do is supported by much research in achieving health and wellness.

These theories explain the diverse results of placebo-controlled clinical trials for TMD pain and other pain conditions which suggest that many different interventions, from splints and medications to physical and cognitive-behavioral therapies and even injections and surgery, can all be used to alleviate TMD pain. The effect of each of these interventions beyond the placebo effect may be small, but they are all significant. Furthermore, by combining these concepts in a multimodal integrative model of care that is based on a human systems approach, the small effects of multiple interventions employed at the same time can result in the greatest positive outcomes. Thus, the evaluation and management approaches proposed in this paper follow these principles.

Principles of Evaluation

The principles of HST can be applied to the evaluation of patients with TMD by employing an inclusive problem list, determining the complexity of the case and following the decision tree for increasing the potential for successful management.

Determine the Problem List. HST expands the traditional “problem list” to include both the physical diagnoses and the contributing factors in each realm. The physical diagnosis is the physical problem that is responsible for the chief complaint and associated symptoms. The orofacial pain disorders noted in TABLE 1 are included in this definition of the scope of dental practice because they have characteristics that involve the oral cavity, maxillofacial area and/or the adjacent and associated structures. Contributing factors include those that initiate, perpetuate or result from the disorder but in some way complicate the problem.

These risk and protective factors are diverse and involve the seven realms of our lives: the physical (physiologic, genetic, molecular); lifestyle (repetitive strain, posture, lifestyle, eating, sleep); emotional (depression, fear, anxiety, anger); social (relationships, abuse, secondary gain); cognitive (attitudes, understanding, honesty); spiritual (faith, beliefs, purpose); and environmental (accidents, pollution, disorganization, hygiene).

Specific risk factors for chronic pain may include peripheral factors such as repetitive strain, oral and postural habits, central mediating factors such as anxiety and depression, and comorbid conditions such as fibromyalgia, somatization and catastrophizing. Protective factors

FIGURE 3. Three levels of change match the three levels of care for increasingly complex patients.

FIGURE 4. Multiple contributing factors can each play a small role at the early stages of a chronic illness, but when combined they will accelerate the condition dramatically.
reduce vulnerability to chronic pain. These factors, which include the level of coping, self-efficacy, patient beliefs (e.g., perceived control over pain, belief that pain is a sign of damage) and social support, can also affect outcomes.

**Determining Complexity.** The level of care for patients can also vary considerably depending on whether their condition is simple or complex. Patients with complex TMD often present with a frustrating medical and dental situation, which may include persistent aggravation of pain, multiple clinicians, long-term medications, repeated health care visits and an ongoing dependency on the health care system. Successful management of these patients is enhanced if the level of complexity is determined and matched to the complexity of the treatment strategy. Singular treatment strategies such as self-care, physical therapy or splints can be quite successful with simple patients who have few contributing factors, but these treatments often fail in complex patients because of the chronic nature of the disease, central sensitization and long-standing maladaptive behaviors, attitudes and lifestyles.

**Decision Tree for Triaging Patients.** Figure 5 outlines the decision tree for sequencing evaluation and management of simple and complex cases. Matching the complexity of a patient with the complexity of the management strategy is the key to success. Once you develop the complete problem list, including contributing factors, it can provide criteria to distinguish simple and complex patients. Complexity of the patient increases with factors such as:
- Presence of multiple comorbid conditions.
- Persistent pain lasting longer than six months.
- Significant emotional problems (depression, anxiety).
- Frequent use of health care services or medication.
- Daily oral parafunctional habits.
- Significant lifestyle disturbances.

In addition, some complex patients warrant deferral of treatment until more complex problems are addressed. The criteria for not treating until these problems are resolved include factors such as:
- Patient has primary chemical dependency.
- Patient has primary psychiatric disorder.
- Patient is involved in significant litigation.
- Patient is overwhelmed with other concerns.

**Patient is not motivated.** Once complexity is determined, the appropriate level of care that matches the complexity of the patient needs to be implemented (Figure 3). For example, a patient with acute self-limiting conditions can be managed with self-care strategy training from a health educator. TMD patients with multilevel problems require a second-order change that uses multimodal treatments as implemented by a single clinician. This integrative care strategy can include multiple treatments, such as splint, exercises, oral habit instruction, medication and palliative self care, to achieve second-order change with improvement over two to four months.

**Use of a Health Care Team.** Complex patients who have major life issues require a third-order change implemented by an interdisciplinary team to achieve success. This transformative care strategy involves the team of clinicians, such as a dentist, physician, health psychologist and physical therapist, working together with the patient to achieve success. Different specialists can address different aspects of the problem in order to enhance the overall potential for success. Teams can be interdisciplinary (one setting) or multidisciplinary (multiple settings). A team approach helps in understanding and managing the whole patient, allows multiple aspects of the problem to be treated simultaneously, improves patient compliance and outcome, saves time and is more economical and more enjoyable because the team works together.

To address every aspect of the problem, treatments may include cognitive-behavioral therapy, counseling, mindfulness meditation, physical medicine treatments, medications, splints, exercises with physical therapy, occlusal therapy and surgery. A consistent philosophy and message to the patient is needed, including the importance...
### TABLE 2

**Self Care for Temporomandibular Disorders**

<table>
<thead>
<tr>
<th>Step</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Apply moist heat or cold to tender muscle and joints.</strong></td>
<td>Heat or cold applications used up to four times per day can relax the muscles and reduce pain.</td>
</tr>
<tr>
<td><strong>Eat a pain-free diet and chew your food on both sides.</strong></td>
<td>Avoid hard foods such as French bread or bagels. Avoid chewy food such as steak or candy. Cut fruits and vegetables into small pieces. Chewing on both sides will reduce strain. If biting into food with your front teeth is painful, cut up your food and chew with your back teeth. Do not chew gum.</td>
</tr>
<tr>
<td><strong>Avoid events or activities that trigger the pain.</strong></td>
<td>Keep a pain diary to review daily activities that aggravate the pain and modify your behavior accordingly.</td>
</tr>
<tr>
<td><strong>Keep your tongue up, teeth apart and jaw muscles relaxed.</strong></td>
<td>Closely monitor your jaw position during the day (waking hours) so that you maintain your jaw in a relaxed, comfortable position. This often involves placing your tongue lightly on the palate behind your upper front teeth (find this position by saying “n”), allowing the teeth to be apart while relaxing the jaw.</td>
</tr>
<tr>
<td><strong>Avoid muscle-tensing habits and activities that put strain on the jaw.</strong></td>
<td>Remind yourself regularly to see if any of these oral habits are present with reminders such as stickers or timers. If noticed, these habits should be replaced with a positive habit such as the “n” tongue position.</td>
</tr>
<tr>
<td>■ Clenching and grinding your teeth (bruxism).</td>
<td></td>
</tr>
<tr>
<td>■ Touching or resting your teeth together.</td>
<td></td>
</tr>
<tr>
<td>■ Biting cheeks, lips or tongue.</td>
<td></td>
</tr>
<tr>
<td>■ Eating hard chewy foods and biting objects.</td>
<td></td>
</tr>
<tr>
<td>■ Resting your jaw on your hand.</td>
<td></td>
</tr>
<tr>
<td>■ Straining the jaw when playing a musical instrument.</td>
<td></td>
</tr>
<tr>
<td>■ Pushing the tongue against the teeth.</td>
<td></td>
</tr>
<tr>
<td>■ Opening your mouth too wide or too long when yawning, singing or during dental visits.</td>
<td></td>
</tr>
<tr>
<td>■ Tensing your jaw or pushing your jaw forward or to the side.</td>
<td></td>
</tr>
<tr>
<td><strong>Practice general relaxation and abdominal breathing.</strong></td>
<td>This helps reduce your reactions to stressful life events and decrease tension in the jaw and oral habits such as clenching.</td>
</tr>
<tr>
<td><strong>Get a good night’s sleep.</strong></td>
<td>Improve your sleep environment. Reduce light and noise and lie on a comfortable mattress. Reduce stimulating activities in the late evening, including computer work and exercise. Avoid sleeping on your stomach.</td>
</tr>
<tr>
<td><strong>Avoid caffeine.</strong></td>
<td>Caffeine can interfere with sleep and increase muscle tension. Caffeine or caffeine-like drugs are in coffee, tea, soda, power drinks and chocolate. Note that some decaffeinated coffee has up to half as much caffeine as regular coffee.</td>
</tr>
<tr>
<td><strong>Use anti-inflammatory and pain-reducing medications.</strong></td>
<td>Short-term use of over-the-counter ibuprofen, naproxen, acetaminophen or aspirin (without caffeine) can reduce joint and muscle pain. If available and compatible with your condition and lifestyle, consider using a combination of an analgesic and muscle relaxant in the evening.</td>
</tr>
</tbody>
</table>
TMD and poor oral habits. Behavior treatment program for all patients presented as an integral part of the overall behaviors should be addressed and to changing maladaptive habits and cases is the only strategy needed. Information about self care should be provided to all patients and in some cases is the only strategy needed. Each type of treatment is discussed briefly.

Reversible Treatments

Self Care. A key determinant of successful management of any musculoskeletal disorder involves educating the patient about the disorder and the necessity of compliance with the self-care aspects of management, including exercise, habit change and proper use of the jaw (TABLE 2). Information about self care should be provided to all patients and in some cases is the only strategy needed.

Behavioral Therapy. Approaches to changing maladaptive habits and behaviors should be addressed and presented as an integral part of the overall treatment program for all patients with TMD and poor oral habits. Behavior modification strategies are the most common techniques used to change habits. Although many simple habits will change when the patient is made aware of them, changing persistent habits requires a structured program facilitated by a clinician trained in behavioral strategies. Habit change using a habit reversal technique can be accomplished when the patient becomes more aware of the habit, learns how to correct it (i.e., what to do with the teeth and tongue) and knows why it is important to correct it.

When this knowledge is combined with a commitment to conscientious monitoring, most habits will change. Progress in changing habits should be addressed at all appointments. In some cases, patients may have significant psychosocial problems that accompany a TMD and may benefit from medication or counseling by a mental health professional. Prior to initiating treatment, a decision should be made as to whether the psychological distress is the primary problem. If this is the case, treatment of the psychological problem is best accomplished first and as an issue separate and apart from the TMD.

Intraoral Splints. Splint therapy can be effective alone or in combination with other treatments for each stage of temporomandibular joint (TMJ) internal derangements and myofascial pain. Although there are many useful types of splints, four are commonly used for TMD: the full-arch stabilization splint, the anterior repositioning splint, the anterior bite plane and the posterior bilateral partial coverage splint. Complications that can occur with the use of any splint include caries, gingival inflammation, mouth odors, speech difficulties and/or psychological dependence on the splint. The most serious complication is major irreversible changes in the occlusal scheme (open bites) that occur because of long-term use of partial coverage splints such as the anterior bite plane and the posterior coverage splint. Splints should not be designed to move teeth orthodontically during treatment of a TMD.

Pharmacotherapy. The most commonly used medications for pain are classified as nonnarcotic analgesics (nonsteroidal anti-inflammatories), narcotic analgesics, muscle relaxants, tranquilizers (ataractics), sedatives and antidepressants.

Analgesics are used to allay pain, muscle relaxants for muscle tension and nocturnal activity, tranquilizers for anxiety, fear and enhancing sleep and antidepressants for pain, depression and enhancing sleep.

Opioid analgesics have their own problems because of the potential for abuse and should be used sparingly and only with patients who have intractable chronic pain, no psychiatric conditions and no history of chemical abuse. If prescribed, clinicians need to follow specific opioid prescribing standards such as use of pain contracts, urine toxicology testing, suspension of medications with violation and other guidelines found at fsmb.org/pdf/2004_gropol_Controlled_Substances.pdf.

Despite the advantages of medications for pain disorders, problems can occur because of their misuse. For this reason, an important goal of treatment for most patients is to eliminate the need for medications long term. With chronic pain patients, termination of current medications should take precedence over prescribing additional ones. Problems that can occur from use of medications include chemical dependency, behavioral reinforcement of continuing pain, inhibition of endogenous pain relief mechanisms, side effects and adverse effects from the use of polypharmaceuticals.
**Irreversible Treatments**

In most cases, TMD problems improve with self care in combination with reversible treatments that encourage the natural healing processes of the muscles and joints. Irreversible treatments involve risk and should be used only if specific criteria are met. This applies to both TMJ surgery and permanent dental stabilization.

**Surgery.** TMJ surgery has become an effective treatment for structural TMJ disorders. However, the complexity of available techniques, the potential for complications, the frequency of behavioral and psychosocial contributing factors and the availability of nonsurgical approaches mandate that TMJ surgery be used only in selected cases that meet specific criteria. The decision to treat a patient surgically depends on the degree of pathology present within the joint, the success or failure of appropriate nonsurgical therapy and the extent of disability that the joint pathology creates. A discussion of individual techniques is beyond the scope of this paper and can be found in the current American Association of Oral and Maxillofacial Surgery (AAOMS) position paper on TMJ surgery. Surgical management may vary from the closed surgical procedure (arthroscopy) to an open surgical procedure (arthrotomy), depending on the degree of disk deformity and degenerative changes. Each of the following criteria, adapted from the AAOMS criteria, should be fulfilled before proceeding with TMJ surgery:

- Documented TMJ internal derangement or other structural joint disorder with appropriate imaging.
- Evidence suggesting that symptoms and objective findings are a result of disk derangement or other structural joint disorder.
- Pain and/or dysfunction of such magnitude as to constitute a disability for the patient.

Prior unsuccessful treatment with a nonsurgical approach that includes a stabilization splint, physical therapy and behavioral therapy.

Prior management of bruxism, oral parafunctional habits and other medical or dental conditions or contributing factors that will affect surgical outcome.

Patient consent after a discussion of potential complications, goals, success rate, timing, postoperative management and alternative approaches, including no treatment. These conditions maximize the potential for a successful outcome but cannot guarantee it. Patients with factors such as fibromyalgia, depression or resistant nocturnal bruxism present with a complexity that has a poor prognosis. In addition, a full knowledge of complications and the reasons for surgical failure can help clinicians make this decision. Once this information is available, a realistic discussion of the prognosis, the patient’s expectations and any complicating factors can help a patient make a correct decision about surgery. Postoperative physical and behavioral therapy should be integrated into the overall surgical management.

**Permanent Dental Stabilization.** Permanent dental treatment may be needed for some patients to provide stable occlusal support and function for the dental and temporomandibular structures. These treatments include occlusal adjustment, restorative dentistry, fixed or removable prosthetics, orthodontics with or without orthognathic surgery. If needed because of poor stability of the dentition, permanent treatment is recommended only after pain has been reduced and normal jaw function restored. The criteria for using secondary dental treatment to maintain comfort and function of the temporomandibular structures include:
The function and stability of the occlusion does not provide adequate orthopedic support. This may be due to missing teeth, skeletal malocclusion or gross interferences in dental function.

The lack of stable dental support is demonstrated to be directly related to aggravation or recurrence of the TMD after primary treatment of the disorder has been successfully completed.

Permanent dental treatment should proceed with the most conservative approach that will provide adequate function and stability of the occlusion. This ranges from occlusal adjustments to restorative dentistry to improve the dental occlusion and orthodontics to orthognathic surgery for changing the position of the teeth and skeletal relationships.

Conclusion

TMDs are common problems that can cause orofacial pain, jaw dysfunction and chronic head and neck pain, with a collective estimated prevalence of at least 20 percent of the general population (Table 1). Because oral and craniofacial structures have close associations with functions of eating, communication, sight and hearing and form the basis for appearance, self-esteem and personal expression, they can deeply affect an individual’s psychological, behavioral and functional status. Thus, understanding TMD with a conceptual model that reflects a comprehensive and integrated problem list that is inclusive and flexible can better prepare clinicians to manage the full diversity of patients, from self-limiting to simple to complex. A human systems approach and related concepts can achieve this goal.

Other Authors’ Critiques of Dr. Fricton’s Paper

Dr. Simmons

The reviewing author has the greatest respect for the authors of the other three manuscripts. They all provide care that helps patients with their pain, dysfunction and/or negative change in quality of life. The comments that are made are for the possible advancement of the knowledge and skills that further our commitment to better treat our patients.

Dr. Fricton’s manuscript is an overview of current whole-body wellness theories and how they relate to the care of the temporomandibular disorder (TMD) patient. He covers the levels of care and the strategies for managing each patient type. He supports most peer-reviewed, evidence-based TMD care and, in appropriate cases, invasive and irreversible care.

TMDs are a group of disorders and not a specific diagnosis. Therefore, treatment should be directed at a specific diagnosis, such as capsulitis, disk displacement with reduction, masseter myalgia, temporal tendinitis, etc. Each diagnosis may have different management techniques. It seems that the TMDs that are described in this manuscript are mainly intracapsular temporomandibular joint (TMJ) disorders.

Conventional wisdom usually directs against the use of the terms “any” and “all patients.” I would like to thank Dr. Fricton for participating in this journalistic endeavor. His patients appreciate his care in relieving their pain and dysfunction.

Dr. Gelb

Dr. Fricton discusses an inclusive philosophy of TMD with human systems theory, a new concept for most dentists. Dr. Fricton states that humans are complex, multidisciplinary and dynamic and present with a multitude of factors regarding onset, perpetuation and progression of their illness. And yet most modern medicine is reductionist and static, looking only at a few factors according to a preconceived paradigm.

Dr. Fricton discusses a flexible, holistic, integrated model to explain the balance between health and illness using a biopsychosocial medical model, cybernetics and chaos theory.

This is a most thought-provoking paper and an excellent explanation of human systems theory for understanding TMD as a chronic illness.

Dr. Raman

Drs. Fricton, Gelb and Simmons’ well-written papers contribute to the knowledge base for dentists.

Dr. Fricton’s description of the theoretical basis of his human systems theory (HST) treatment philosophy is reasonable. However, the crucial step is the actual application of this approach for a patient in clinical practice. That is where the proverbial rubber meets the road. He states that it starts with “seeing the whole patient through the eyes of the biopsychosocial medical model.” Prominent proponents of this model such as Charles Greene, DDS, completely dismiss any occlusion-altering approach. Occlusal changes affect the mandibular relationship to the maxilla. When there is a discrepancy in this relationship, correcting that would be “a change from outside to achieve a new level of existence,” i.e., a third-order change. In his list of third-order changes, Dr. Fricton fails to include that which dentists are uniquely qualified to do: correct malalignment of mandible to cranial base. Physiologic neuromuscular dentistry (PNMD) does that exquisitely, guided by objective physiologic parameters.

Dr. Fricton’s definition of complex patients fits almost every one of my patients. He states that resolution is rarely achieved with complex patients. The PNMD approach has been very successful in resolving medically diagnosed fibromyalgia, migraine and other clinical manifestations of TMD.

55. Turner JA, Bristor H, Huggins KH, Truelove EL. Catastrophizing is associated with clinical examination findings, activity interference, and health care use

Dr. Fricton’s Response to Critiques

First, I want to thank the guest editor, Dr. Jenkins, for his innovative approach in this issue, and the three contributing authors, Drs. Gelb, Simmons and Raman for their thoughtful and engaging comments on their diverse approaches to managing TMD. It is only through this type of knowledge exchange and discussion that we will be able to improve the broad understanding and care of TMD patients. After reviewing the three authors’ responses to each of the papers, some general as well as specific comments are warranted.

Evidence-based dentistry is the conscientious, explicit and judicious use of the best and most current evidence in making decisions about the care of each patient. As Turpin stated, “The purpose of using the evidence-based approach is to close the gap between what is known and what is practiced, and to improve patient care based upon informed decision making.” Systematic reviews of randomized clinical trials (RCTs) are considered the highest quality of scientific validation because they measure both the quality of RCTs and the power of combining outcomes from multiple studies (FIGURE).

With this in mind, systematic reviews of RCTs employing placebo-controlled clinical trials for TMD pain have demonstrated the efficacy of many different interventions, including intraoral splints, self care, exercise, medications, physical therapy, transcutaneous electroneural stimulation, cognitive-behavioral therapies, injections and TMJ surgery. Each addresses one or more of the many factors involved in the etiology of TMD, depending on the individual diagnoses and characteristics of the patient.

FIGURE. The hierarchy of scientific evidence.

THE AUTHOR, James Fricton, DDS, MS, can be reached at fricton1@umn.edu.
Response to Dr. Gelb’s critique

Dr. Gelb recognizes the importance of the concept that should be the basis for all TMD evaluation and treatment: TMD is a chronic illness with a multitude of contributing factors. His innovative paper shows how protection of the airway is one such factor that is paramount to survival and can play a role in the development and subsequent management of TMDs. Likewise, many other contributing factors complicate TMDs and are as important for survival. Examples include the patient with a closed TMJ lock as a result of an assault who now has post-traumatic stress disorder (PTSD), or the patient with masseter pain from being sexually abused who is now depressed and suicidal, or the patient with temple headaches from the anxiety of being a single working mother of two children, or the patient with jaw pain caused by severe nocturnal bruxism due to the side effects of antidepressant medication for ADHD. These types of patients exist in all TMD clinics and the many other contributing factors need to be recognized and managed as with any chronic illness.

Response to Dr. Simmons’ critique

Dr. Simmons astutely points out that there is no “one-size-fits-all” approach to TMD. Both the specific TMD diagnoses (muscle, joint or both) and the list of contributing factors (behavioral, cognitive, emotional, social, comorbid conditions, etc.) must be identified for each patient. Then the judicious use of these evidence-based interventions as part of an interdisciplinary and integrated approach to care for an individual patient will result in the greatest positive outcome.

Response to Dr. Raman’s critique

Dr. Raman also wisely points out that the crucial step for any TMD philosophy is its actual application for patients in clinical practice. He states, “This is where the proverbial rubber meets the road,” and provides an important rationale for an evidence-based approach. What works for the few patients who accept a specific treatment approach by a single dentist must also work for many patients who receive the same treatment by other dentists.

In this regard, systematic reviews of RCTs employing occlusal treatment as a primary treatment for TMD, including occlusal adjustment, restorative dentistry, orthodontics and orthognathic surgery, either have not had sufficient clinical trials or have not demonstrated consistent efficacy. Although individual patients may improve after these interventions, the results of studies of larger populations are inconsistent. Because of these negative findings and the readily available TMD treatments that have scientific support for their efficacy and, with the exception of surgery, encourage natural healing and repair with fewer adverse events, occlusal treatments are currently not recommended as a primary treatment for TMD.

These recommendations do not mean that occlusion has no relevance to TMD or that dentists should ignore occlusion. For all dental patients, occlusion is critical in providing orthopedic support for stability, comfort and function of the teeth and is essential to eating, appearance, communication and personal expression. Furthermore, patients with TMD often need dental treatment as part of normal dental care. This is particularly true when malocclusion does not provide adequate orthopedic support because of missing teeth, dental or skeletal imbalances or gross interferences. Thus, providing sound evidence-based dental care to these patients is still of paramount importance. Safe dental treatment is also important because dental treatment can cause TMD injuries if the mouth is opened too wide or for too long a period.

Conclusion

I believe that most clinicians who care for patients with TMD realize that there is both an art and a science to TMD treatment. The art is important when patient complexity requires recognition of the multitude of contributing factors and formulation of a personalized approach that also maximizes the outcomes of evidence-based treatments. Although we are dentists first and are well trained to treat the teeth and occlusion, we need to recognize that when managing a chronic illness, we must understand and manage the whole patient, even if it involves bringing in other clinicians with expertise we may not have.

Furthermore, there is still a place for empirical experience-based approaches to TMD, because we cannot always rely on science-based approaches that only estimate what strategies work best. But, as Isaac Asimov states, “There is a single light of science, and to brighten it anywhere is to brighten it everywhere.” Let’s continue to bring science to the treatment of TMD.

Note: For those interested in understanding the strategies and paradigms of a human systems approach to chronic pain, including TMD, the University of Minnesota in coordination with the International MYOPAIN Society (myopain.org) offers an online MOOC course on the topic at coursera.org/course/chronicpain.

Informed Consent

Informed consent is paramount for the TMD orthopedic dentist. Some dentists have less than optimum formal education in the assessment, diagnosis and treatment of TM disorders but we are legally liable in most states for diagnosing and treating these disorders. This makes for an environment where the dentist providing TMD orthopedic care must make sure that his or her patients have a clear concept of the treatment that is proposed for them and the research supporting that care. Patients have the right to decide between conservative and invasive care in treating disorders of the body.

Definition of TMD Orthopedics

TMD orthopedics is the assessment, diagnosis and management of orthopedic disorders of the temporomandibular joint (TMJ). Anterior repositioning appliance (ARA) therapy for TMJ internal derangements is successful in long-term recapturing of disks in reducing and nonreducing joints at a rate of 64 percent and in regenerating degenerated condyles in some cases. ARA therapy for TMJ internal derangements is subjectively successful in relieving symptoms in reducing and nonreducing disk displacement TMJs in this study at an average rate of 94.5 percent.

The American Association of Dental Research (AADR) defines temporomandibular disorders (TMDs) as a group of musculoskeletal and neuromuscular conditions that involve the temporomandibular joint (TMJ), the masticatory muscles and all associated tissues.

Informed Consent

Informed consent is paramount for the TMD orthopedic dentist. Some dentists have less than optimum formal education in the assessment, diagnosis and treatment of TM disorders but we are legally liable in most states for diagnosing and treating these disorders. This makes for an environment where the dentist providing TMD orthopedic care must make sure that his or her patients have a clear concept of the treatment that is proposed for them and the research supporting that care.

Patients have the right to decide between conservative and invasive care in treating disorders of the body. Dental patients may decide whether they want...
to have a tooth extracted or to have endodontic care. Cancer patients decide whether they want care or not. Proper informed consent requires that patients are informed of treatment methods that are available for their disorder.\textsuperscript{9} There is adequate peer-reviewed, evidence-based literature to support orthopedic anterior repositioning appliance (ARA) care for some TMD patients.\textsuperscript{7,12} If informed consent does not include informing an appropriate group of patients about TMD orthopedic ARA care, then proper informed consent has not been attained.

The author spends three hours conducting a history, examination and consultation with each new TMD orthopedic ARA care patient to ensure that there is clear informed consent before anything more than emergency care is provided. TMD orthopedic ARA therapy is complex care, and dentists should seek education and clinical training before attempting to provide these services to patients.\textsuperscript{13} Successful ARA therapy depends on the knowledge and skills of the clinician and it has limitations.\textsuperscript{14}

The author has developed a three-page consent form for initial active TMD orthopedic ARA care and, when needed, an additional three-page consent form for more durable, long-term occlusal care and retention.

**Human Orthopedic Fundamentals**

The American Academy of Orthopaedic Surgeons’ definition states that this specialty’s scope of practice includes the diagnosis, care and treatment of musculoskeletal disorders, including the body’s bones, joints, ligaments, muscles and tendons.\textsuperscript{15} The AADR defines TMDs as those that “encompass a group of musculoskeletal and neuromuscular conditions that involve the temporomandibular joints (TMJs), the masticatory muscles and all associated tissues.” Weldon E. Bell, DDS,\textsuperscript{16} said, “A good understanding of the basic principles of orthopedics should be fundamental to everyday dental practice. It is prerequisite to the rational management of temporomandibular disorders.” Most TMDs are an orthopedic disorder, with magnetic resonance imaging (MRI) showing anatomic abnormality in the TMJ in greater than 80 percent of TMD patients.\textsuperscript{9,17} In one recent study, 88 percent of 58 consecutive TMD patients seen in a referral-based practice had abnormal MRIs when read by an oral and maxillofacial radiologist.\textsuperscript{9} Many TMDs are the result of injury to ligaments, muscles, tendons, nerves, vascular or joint structures.\textsuperscript{18-21}

Wiesel and Delahay’s textbook, *Essentials of Orthopedic Surgery*, states that ligamentous injuries occur as a result of acute macrotrauma and represent a macrotrauma process. In contrast, injuries to tendons can be both acute and chronic processes. Chronic tendon overload represents the classic microtraumatic injury in sports medicine. These injuries occur at the sites of high exposure to repetitive tensile overload.\textsuperscript{22} Macrotrauma is defined as either an impact blow or hyperextension of a joint system.\textsuperscript{21} The conclusion can be drawn that a macrotrauma event is required to tear the ligaments that hold the TMJ disk in place and therefore displace the disk from a normal physiologic position to an abnormal pathologic position. Displacement of TMJ disks is the causation of TMJ internal derangements.\textsuperscript{2} This would exclude normal function and occlusal dental conditions from causation of internal derangements of the TMJ. It would also exclude parafunction of the mandible as causation of TMJ disk displacement, as this is not defined as a macrotrauma event. There are six ligaments (Okeson includes the joint capsule in ligaments) in or associated with each human TMJ.\textsuperscript{7}

MRI results were obtained on 30 infants and young children from age 2 months to 5 years. None of the 60 joints that were examined had a displaced TMJ disk.\textsuperscript{23} Therefore, humans are not usually born with a TMJ internal derangement.

Isberg et al. described an arthrokinetic reflex in the muscles of mastication associated with disk displacements.

“Continuous muscle activity was provoked by disk displacements and ceased when the disk position was normalized on mouth opening, only to occur again every time the disk became displaced on mouth closure.” These findings were in line with those previously published on limb joints, which indicated that joint derangements are a cause of muscle hyperactivity.\textsuperscript{10,21} Farrar reported that the evidence was “conclusive and irrefutable” that TMJ displaced disks produced the symptoms of myofascial pain dysfunction.\textsuperscript{24} There is literature to support that recapturing a TMJ disk can relieve symptoms of the arthrokinetic reflex.\textsuperscript{25} Relieving abnormal muscle activity can relieve pain of muscle origin.

Cyriax, in his *Textbook of Orthopaedic Medicine*,\textsuperscript{11} states that muscle spasm should not be treated as a primary disorder when there is a concomitant joint disorder. He maintains, “If arthritis or a degree of internal derangement can be
abated, the protection given to the joint by the muscles becomes unnecessary.” Cyriax also states, “No structure of the body is so quickly altered by influences outside itself as muscle. Once a muscle has wasted considerably, even though no disease of the muscle itself has ever occurred, it may never regain full bulk.” A TMJ with a disk displacement (internal derangement) may cause abnormal muscle activity (contraction) around the joint. The abnormal muscle activity may then cause the patient to experience muscle pain through trigger points, headache, neck ache, autonomic phenomena such as dizziness and disequilibrium, fatigue in craniofacial muscles and mandibular dysfunction. The question for the TMD orthopedic dentist is, “Why is that muscle in a state of continuous activity, contraction, splinting or spasm?”

Knowledge of the anatomy and a systematic approach are the fundamentals of palpation.28 A widely accepted method to determine muscle tenderness and pain is by digital palpation. A healthy muscle does not elicit sensations of tenderness or pain when palpated.7,27 While tenderness of a particular structure may be present in the majority of individuals, tenderness should not be present in a healthy, optimally functioning structure. Consequently, while tenderness may be “the norm” for that individual, it is not truly normal and indicates a subclinical dysfunction. So the conclusion can be drawn that palpated normal structures should not elicit pain.

For proper orthopedic evaluation, joint motion must be assessed and measured.28 The consensus among a large group of TMD authorities is that mandibular normal opening range is 40-50 millimeters, and the normal left and right lateral movements are 8-12 millimeters.28

TMD care was covered in orthopedic medicine and surgery textbooks until the 1980s,11,29 when physicians and surgeons turned this area of care over to the dental profession. As testimony to this, Campbell’s Operative Orthopaedics, fourth volume, 11th edition (4,899 pages) and Wiesel and Delahay’s textbook, Essentials of Orthopedic Surgery21 (615 pages) do not have the words “temporomandibular” or “TMJ” in either of their indexes. It is now the responsibility of the dental profession to provide orthopedic care for the only joints that the medical community does not treat. Many TMDs are orthopedic disorders and orthopedic care for some TMDs is appropriate.16

It is now the responsibility of the dental profession to provide orthopedic care for the only joints that the medical community does not treat.

The TMD Orthopedic Dentist
An orthopedic TMD dentist is a dentist who may:

- Treat TMDs by utilizing orthopedic appliances to reposition the mandible to diminish the load on the TMJ.2,10,31
- Reposition the mandible to attempt to recapture displaced TMJ disks that are reducing.7,9
- Reposition the mandible to place the condyle in a more physiologic position to diminish an arthrokinetic reflex (protective muscle splitting).10,11,21
- Manipulate the mandible to reduce TMJ disks that may have been reducing and now are acutely nonreducing.7,12,13
- Manipulate the mandible to mobilize the TMJ condyle and/or disk.7,12,33
- Use injection techniques to diagnose and treat TMDs.7,12,14-17
- Use physical medicine to treat TMDs7,12,18 and, when indicated, provide long-term reversible and irreversible occlusal care for orthopedic TMDs.1,7,29,40

TMD orthopedic dentists may treat sleep apnea13,41 and dental malocclusions,39,42 but these disorders are not classified as TMDs. TMD orthopedic ARA care that is peer reviewed and evidence based is clearly available for some TMDs.25,43-48 The American Dental Association (ADA) publication Dental Practice Parameters for Temporomandibular (Craniomandibular) Disorders1 supports most of the procedures described in the above definition of an orthopedic TMD dentist. The ADA Council on Dental Care Programs40 also supports most of these procedures. Dentofacial orthopedics is a part of mainstream orthodontic care utilizing functional appliances and Herbst appliances.39

Value of Normal Disk Position
Hall49 stated that data now support the assumption that a normal TMJ disk position assists in alleviating pain, prevents the gross degenerative changes of osteoarthritis and promotes growth of the mandible. Based on these data, he believes there is a strong argument for including disk recapture as an important goal of any treatment for the painful joint with a displaced disk that reduces.

Nickerson,50 using Boering’s 30-year study of the natural course of TMJ degeneration,51 showed that reestablishing normal disk position protects the joint from degenerative joint disease and osseous breakdown leading to occlusal collapse and facial distortion. Nickerson50 stated that under certain conditions there is a relationship between TMJ disk displacement and masticatory
Musculoskeletal pain. He suggested that there is positive value to having the disk in a load-bearing position, and that the primary focus in treating patients with disk displacement with reduction should be an attempt to recapture the disk.

Schellhas et al. used MRI to show the negative effects of disk displacement of the TMJ in children. They found that children with retrognathia and mandibular asymmetries usually have advanced degrees of TMJ derangements with characteristic shifts toward the most deranged joint. They proposed that in the growing facial skeleton, internal derangement of the TMJ either diminishes or stops condylar growth, resulting in facial distortion.

Lundh and Westesson discovered that recapturing a displaced disk effectively eliminated pain and dysfunction in patients in whom a normal relationship between the disk and the condyle can be established. In their study, ARA therapy was deemed superior to either flat plane appliance therapy or no treatment.

There is adequate literature to support the value of having the TMJ disk in a normal anatomical and load-bearing position, and there are definite negative consequences to having a displaced TMJ disk.

A study by Simmons and Gibbs included 53 joints with disk reduction and 45 joints with disks recaptured with ARA, yielding a 3-D recapture rate of 85 percent. Recapture or improvement in disk position was achieved in 91 percent of reducing, 28 percent of nonreducing and 63 percent of all joints with internal derangements. No disk status was worsened.

**TMD Orthopedic ARA Therapy Care**

Treatment of most human disorders usually has as the goal a return to a more normal physiologic state. TMD orthopedic ARA therapy’s goal is to return the mandibular condyle and the contents of the TMJ to the most normal physiologic orthopedic condition attainable. Imaging is necessary for proper bite positioning and has shown recapture with MRI in 85-96 percent of patients with disk displacements with reduction. Lundh and Westesson showed normal anatomy of the TMJ in their TMJ dissection videos (Figure 1) as the reference for normal, and others have validated this. FIGURE 2 shows abnormal TMJ anatomy demonstrated as disk displacement with reduction. Some patients with disk displacement with reduction start as shown in Figure 1, with teeth in maximum intercuspal position, and through macrotrauma become as shown in Figure 2, with teeth in maximum intercuspal occlusion.

Occlusal changes are possible from displacement of the TMJ disk. When the patient is awake, the reflex to swallow (deglutition) occurs once per minute and causes the maxillary teeth to index into a mandibular orthopedic appliance (Figure 3) that is constructed to cause the mandibular condyle to return to a more physiologic position in the glenoid fossae. Over a period of one to two months, the patient adapts to the new swallowing occlusal index in the orthopedic appliance. Patient symptoms are usually relieved in three to six months by the normalization of the contents of the TMJ, which reduces the protective muscle splinting (arthrokinetic reflex) that may have caused the pain the patient was experiencing. Research has shown that the muscles associated with the TMJ sense where the condyle is positioned more than they sense where the disk is positioned. Lundh and Westesson felt that replacement of the disk onto the condyle may not be absolutely necessary and that a protrusive change in condylar position may be sufficient to give relief of symptoms in some cases. During sleep patients swallow only three times per hour so they need an appliance similar to that popularized by Farrar (Figure 4) that does not rely on swallowing to compensate for the injured ligaments of

---

**Figure 1.** Normal TMJ anatomy (adapted from Lundh and Westesson).

**Figure 2.** Abnormal TMJ anatomy—TMJ disc displacement with reduction (adapted from Lundh and Westesson).

**Figure 3.** Awake mandibular orthopedic repositioning appliance.
the TMJ. This is accomplished by wearing an asleep appliance that holds the condyle in the same position as the awake appliance without relying on the swallow reflex.12,57,64,65

The author used the Farrar appliance for asleep wear with all research papers, but now uses the appliance shown in FIGURE 5 because of improved retention of orthodontic corrections. The patient is required to wear an appliance 24 hours per day, except for oral hygiene care.12,57,64,66 After accomplishing maximum medical improvement, the patient is asked to continue wearing the appliances for an additional three months to prove that his or her condition is stable.40 End of active care records are then taken for the patient. For long-term retention of physiologic condylar position, the less durable acrylic awake appliance is either replaced with a more durable mandibular overlay partial denture (chosen 5 percent of the time by the author’s patients), or patients have the option of orthodontic care to close their posterior open bite and finalize their teeth to the new mandibular position (chosen 93 percent of the time by the author’s patients) or crowns and/or bridges, which are utilized only if the patient needed full-coverage dental restorations pretreatment (chosen 2 percent of the time by the author’s patients). ARA therapy is not focused on the dental occlusion other than as a method of retaining the mandibular condyle in a more normal physiologic position to compensate for the inability of torn ligaments to hold the contents of the joint in a physiologic position. The asleep appliance is continued for the remainder of the patient’s life as a retainer of teeth position and to keep the mandibular condyle in the more normal position in the glenoid fossae during the low swallowing environment of sleep63 because injury to the ligaments are permanent and cannot provide this function.22

Only patients who have some degree of pain, dysfunction and/or negative change in quality of life (PDQ, a term trademarked by the author) warrant TMD orthopedic ARA care.58,67,68 If a patient who does not have PDQ elects to have orthopedic ARA care for a TMD a clear informed consent relevant to this issue is strongly recommended.

Superiority of ARA Therapy to Flat Plane Appliance Therapy

Lundh et al.61 evaluated 70 patients with TMJ internal derangements. They divided treatment of the patients into anterior repositioning appliance therapy, flat plane appliance therapy and a control group with no appliances. Both appliance groups had reduced joint tenderness, but the ARA group demonstrated a significantly greater improvement with respect to internal derangements and symptoms. Anderson et al.69 divided 20 patients with internal derangements into two groups and treated one group with maxillary flat plane appliances and the other with ARA. After 90 days, the ARA group experienced a significant reduction in dysfunction and symptoms. The flat plane appliance group experienced no change in dysfunction and two patients progressed to closed lock (disk displacement without reduction).

In 2002, Brown and Gaudet70 published a long-term, multisite study of 2,104 treated, 250 untreated and 44 long-term treated TMD patients. A valid and uniform assessment of treatment outcomes across a large number of practices was assured by utilizing the TMJ Scale (Pain Resource Center, Durham, N.C.). This paper showed that untreated TMD patients do not improve spontaneously over time and that patients treated with a variety of active modalities achieve clinically and statistically significant levels of improvement. The use of ARA therapy produced superior results compared to flat plane appliance therapy.

Symptom Relief From ARA Therapy

Simmons and Gibbs25 found that at maximum medical improvement (MMI), symptom improvement from ARA therapy was 81-87 percent in patients with both disks either in normal position or recaptured position and 76 percent in patients with at least one disk that did not recapture. Occipital headache, which was the most common complaint, occurred in 94 percent of the patients. Headaches after MMI were unchanged in 1 percent of the patients, better in 33 percent and eliminated in 66 percent.
TABLE 1 shows pretreatment and posttreatment symptom levels for each disk status posttreatment and a statistical analysis. All classifications of disk displacement had significant positive results with ARA therapy.25

**TMD Orthopedic Assessment, Diagnosis and Management Appointment Sequence**
1. History, examination and consultation appointment.
2. Diagnostic appointment.
3. Appliance delivery appointment.
4. Range of motion, anatomic site palpation, follow-up evaluation of presenting symptoms at three- to six-week intervals for six to nine months.
5. End of reversible care appointment.

**Posterior Open Bite**
TMD orthopedic ARA therapy creates a posterior open bite as the condyles are moved forward in the fossae to recapture disks or to move the condyles to a more physiologic position in the fossae when the disk(s) cannot be recaptured.71,72

A posterior open bite is an expected and acceptable result of ARA therapy and is compensated for by continued wearing of the active treatment intraoral appliance or a more durable overlay partial denture, or it is corrected by crowns and/or bridges or orthodontic care.40,73 Patients must be informed of the possible creation of a posterior open bite before initiation of ARA therapy.

**Therapeutic Injections for TMDs**
Orthopedic care of the TMJ may utilize various injection techniques.12,13,37 Waldman34 stated that injection of the TMJ is indicated as an important component in the management of TMJ dysfunction, the palliation of pain secondary to internal derangement of the joint and in the treatment of pain secondary to arthritis of the joint. Injection of local anesthetic is used to diminish trigger points in muscle bellies and tendons.35,74 Bell17 stated that the use of local anesthetic in the treatment of orofacial pains is very effective. To be successfully treated, some pain syndromes require the use of local anesthetic injections. Proliferative therapy injections are used to strengthen and thicken injured tendons, ligaments and joint capsules.73-78

Proliferative therapy injections were not used in any research paper referenced in this article, but are now an integral part of the author’s care of TMD patients.

**Untreated Cohort of TMD Patients Versus Patients Treated With ARA and Injection Techniques**
On June 7, 2007, letters were sent to 420 patients who had decided not to have treatment and who had completed a TMJ Scale test from 10 years to one year prior. The letter asked the patients to complete a new TMJ Scale if they had not had treatment for their TMD. Forty-five test replies were received. **TABLE 2** shows the cohort of 45 untreated TMD patients compared with 100 consecutive patients treated in the author’s office using ARA therapy and therapeutic injections. This untreated cohort versus treated patients shows a control and has a statistical significance of <0.001.

**Long-term, 10-year Follow-up on ARA Patients**
Of the 48 patients who finished active orthopedic ARA care in a study by Simmons and Gibbs,25 39 patients were provided more durable, long-term occlusal care. Beginning on April 8, 2006, MRIs were obtained on these patients to determine long-term status of their TMJ disks. The author’s durable occlusal care options for long-term retention of condylar position were described earlier. These patients finished more durable occlusal care from six to 12 years before this data was recorded, with an average of 10 years.

Of the 39 patients who finished more durable occlusal care, 20 agreed to long-term follow-up MRIs. Of the 40 joints in this long-term study, 25 had disks that reduced on mouth opening before treatment. Of these, at appliance delivery there were 20 joints for which disks were...
recaptured with ARAs. That yields a 3-D initial disk recapture rate of 80 percent (20/25) in this patient population.9 All MRIs were read by a board-certified oral and maxillofacial radiologist (S. Julian Gibbs, DDS, PhD). Twelve joints retained the recapture of disk at long-term MRI evaluation, for a 60 percent (12/20) retention of initial TMJ disk recapture in this patient population and a long-term recapture rate of 48 percent (12 recaptured disks long term/25 joints with reducing disks before treatment). Some of these patients had experienced significant trauma to the mandible since finishing care.

At long-term follow-up, six joints had new recapture of the disks that were not recaptured initially. Three of the six were displacement with reduction and three were displacement without reduction before treatment. Three disks that recaptured long term from the reducing group that did not recapture initially, added to the 12 disks that were disk displacement without reduction prior to treatment. When the three new recaptures from the displacement without reduction group are added to the final count of recaptures, the total is 18 disks recaptured long term (12 retained from initial recapture, three new recaptures from reducing group, three new recaptures from nonreducing group) of the 28 joints (25 reducing and three nonreducing), for a recapture rate of 64 percent (18/28).

Four patients had the six surprise disk recaptures. All of these patients were compliant and reported that they wore their maxillary ARA every time they slept following completion of more durable occlusal care.

Subjective percent improvement statements were signed by each of the 20 patients who had a long-term MRI. The average subjective symptom relief in this group was 94.5 percent of presenting symptoms relieved. Eight of the patients reported that 100 percent of their presenting symptoms were gone at an average of 10 years’ follow-up.

Regeneration of Mandibular Condyles From ARA Therapy and Long-term Retention

Several of the long-term follow-up patients showed regeneration of the mandibular condyles as a result of their ARA therapy, durable occlusal care and long-term retention. Figures 6A-B and 7A-B show one of these regeneration cases.

Retention of Orthodontic Care and Condylar Position

Joondoph79 devoted a complete chapter in a textbook to his findings that postorthodontic treatment results after ARA therapy completely relapsed over time (four years). In a recent study by Lenz and Harris,80 orthodontic relapse was 50 percent of dental correction and 115 percent of skeletal correction at 10 years posttreatment in a group of dental students who were treated by their hometown orthodontists. Lenz and Harris state that there is little to suggest long-term stability of an orthodontic result. Aggressive lifetime retention appears to be the only predictable method of permanently retaining orthodontic corrections.73 The author’s cases in this report were all aggressively retained by a maxillary anterior retaining appliance to be worn during sleep for the rest of the patient’s life. Proper aggressive lifetime retention solves ARA case relapse.

Conclusions

In Katzberg and Westesson’s opinion,58 protrusive appliance therapy, followed by permanent alteration of the dental occlusion to match the therapeutic position, is an effective method of diminishing symptoms related to disk displacement with reduction. Okeson7 states that when occlusal therapy is indicated to resolve the symptoms of a TMD, the specific treatment goals are

determined by an occlusal appliance that has successfully diminished the symptoms. If an intraoral appliance has diminished the signs and symptoms, a similar occlusal condition may be introduced by irreversible occlusal therapy.

Simmons and Gibbs concluded a 1997 paper by stating that if the largest category in a consecutive complex chronic TMJ pain population is disk displacement with reduction, and 85 percent of these will recapture when the condyle is placed in the Gelb 4/7 position (physiologic normal), and symptomatic relief following ARA therapy has been shown by both subjective and objective criteria in patients with other categories of disk disorder, then ARA should be the appliance of choice for this patient population.

Orthopedic care is appropriate for some TMDs. ARA therapy for TMJ internal derangements was successful in long-term recapturing disks in reducing and nonreducing joints in this patient population at a rate of 64 percent. ARA therapy for TMJ internal derangements was subjectively successful in relieving symptoms long term in reducing and nonreducing joints in this patient population at an average rate of 94.5 percent. Based on the evidence presented in this study, the orthopedic TMD dentist utilizing ARA therapy may now regenerate TMJ condyles in some patients.

23. Passani D, Salas E, Martinez A, Isberg A. Prevalence of temporomandibular joint disk displacement in infants and
Dr. Gelb

The TMJ is a synovial joint, with a disk and two compartments working in a class-three lever system that follows orthopedic principles.

Dr. Simmons makes us aware of how little time is spent in the undergraduate dental curriculum on TMD diagnostic competency, yet the dentist is legally liable in most states to diagnose and treat these disorders.

Isberg described the arthrokinetic reflex, which was also seen by Cyriax, a physician, and by Gelb and Farrar and other orthopedically minded dentists to explain continuous muscle activity, contraction, splinting and spasm. This counters a purely neuromuscular approach in favor of orthopedic anterior repositioning therapy.

Informed consent is a very important part of anterior repositioning appliance (ARA) therapy, as the teeth are secondary and bites are often altered.

Dr. Simmons’ orthopedic approach using ARA therapy to recapture disks has been well documented. Although disk recapture is preferable, joint decompression with pseudo-disk formation is also successful in reducing symptoms.

Dr. Simmons states that his cases usually require case finishing: Two percent crown and bridge, 5 percent permanent appliance and 93 percent orthodontics.

In children, I agree that almost 100 percent of cases would be finished orthodontically to a Gelb 4/7 position and open airway with nonextraction expansion functional and fixed orthodontics (Miew, Hang, Singh, Mahoney, Miraglia, Rondou).

CONTINUES IN SIDE BAR ON 547
With adults, we attempt to wean our patients off daytime appliance therapy using cognitive behavioral therapy, starting with lips together, teeth apart, tongue to the spot, sternum up, core engaged, with the feeling of a string lifting the head.

In my practice, 5 percent require some dentistry such as anterior guidance or crown and bridge. Another 10 percent are sent for orthodontic evaluation.

Approximately 85 percent are finished with only a nighttime appliance such as a Farrar or AC oral appliance.

Given the epigenetic and iatrogenic changes to our faces and occlusions, a posterior open bite should not be viewed as abnormal. It is preferred to a compressed TMJ and closed airway position.

Dentistry has been retruding the jaw, compressing the joint and closing the airway for 85 years. The time has come for change and for the orthopedic principles of anterior repositioning therapy as explained by Dr. Simmons.

Dr. Raman

Dr. Simmons’ paper describes his treatment approach of anteriorly repositioning the condyle to recapture the disk. The PNMD approach does include this concept to achieve optimal results, as a dislocated articular disk is not congruent with conical muscles. While it is agreed that a displaced disk elicits muscle hyperactivity, a displaced disk is not a prerequisite for muscle hypertonicity. A poor mandibular alignment that necessitates increased activity of the temporalis muscle[s] also leads to myofascial pain dysfunction (MPD). So MPD syndrome could precede disk displacement.

Dr. Simmons dismisses any other causation besides macrotrauma for disk displacement. All joints are protected by ligaments at the limits of their range of motion. Normally, the muscles stabilize the joints. If a joint chronically functions at the limits, it is “leaning on the ligament.” Such chronic overloading of ligaments has been shown to damage them and to lead to dislocation of articular cartilage.

Further, he suggests that there is some positive value to having the disk in a load-bearing position, and that the primary focus in treating patients with disk displacement with reduction should be an attempt to correct this condition. Normal function of crushing food — the activity of maximal load on the TMJs — occurs with teeth apart. However, if the teeth are together and maximal load is applied, the TMJ experiences load with the disk in the ideal position. Of course, this describes clenching, which is parafunction. Post-condylectomy patients who have been treated with PNMD concepts are functioning well — able to chew food and remain pain-free — even in the absence of an intact condyle-disk-fossa assembly.

Dr. Simmons also states that anterior repositioning appliance (ARA) therapy for TMJ internal derangements is subjectively successful in relieving symptoms long-term in reducing and nonreducing joints at an average rate of 94.5 percent. While subjective improvement is what matters to patients, is it possible to treat a case to subclinical asymptomatic status that would be more vulnerable for relapse or dysfunction? Why not use objective data such as EMG to augment subjective reports to guide treatment?

REFERENCES

Dr. Simmons’ Response to Critiques

Response to Dr. Fricton’s critique

Dr. Fricton states that a posterior open bite is an adverse event related to anterior repositioning appliance (ARA) therapy. In most cases, a posterior open bite is a predictable and expected part of ARA therapy. The patient must be informed before treatment1 of this mid-treatment event so that he or she expects possible further treatment to correct the usual dental occlusal disharmony created by ARA therapy.2,3 Other areas of dentistry have similar treatment outcomes. When a molar endodontic procedure is completed, the tooth typically needs a crown.

Response to Dr. Gelb’s critique

Dr. Gelb recommends weaning most TMJ internal derangement patients off their awake ARA therapy appliance and allowing them to return to their pretreatment dental occlusion. This practice is utilized by a large number of dentists who provide ARA therapy and is recommended by some guideline texts.4 The dental occlusion usually changes secondary to TMJ disk displacement when a thicker disk is exchanged for a thinner posterior attachment tissue. Therefore, the spacer between the condyles and fossae usually changes with chronic TMJ disk displacement and the forces of the masticatory elevator muscles. Teeth position adapts to changes in the TMJ condyle position and also to changes to the teeth throughout life.5 Most TMJ disorder patients are chronic pain patients,6 and therefore, the dental occlusion has usually had time to adapt to the pathological position of the condyles in the fossae.7 This is the reason for the need for occlusal therapy after reversible ARA therapy. When people have posterior teeth, they have a reflex desire to occlude their maxillary and mandibular posterior teeth to swallow approximately 1,500 times per day and to masticate food.8,9 If patients are allowed to return to their pretreatment dental occlusion, they may return to some degree of their pretreatment signs and symptoms because ligaments that once held the TMJ components in a physiologic position do not heal to pretrauma condition.

Response to Dr. Raman’s critique

Dr. Raman questioned the concept that macrotrauma is the etiology of TMJ disk displacement disorders. There are several references in the peer-reviewed literature that lead one to believe that trauma is the major cause of TMJ intracapsular disorders.10,11 Wiesel and Delahay’s textbook, Essentials of Orthopedic Surgery,14 which was quoted in the manuscript, is used by medical schools to teach third- and fourth-year medical students the basics of orthopedic surgery. Dr. Wiesel is the professor and chair of the Department of Orthopedic Surgery at Georgetown University Medical Center. Dr. Delahay is professor and vice-chair of the same department. The textbook is in its third edition, so any errors would have been corrected by the third edition. Ten other orthopedic surgeons contributed to this textbook, which states that “ligamentous injuries occur as a result of acute macrotrauma and represent a macrotrauma process.” TMJ disks are held in place by ligaments.4,15 The references that Dr. Raman cites relating to joint overload as a cause for articular cartilage displacements are both related to lower limb weight-bearing joints.16,17 The human TMJ disk is fibrous connective tissue and is not cartilaginous.8,15,18 Human maxillary and mandibular teeth contact each other for only 20 minutes out of 24 hours in a normal person.8,9 If chronic overloading of the TMJ ligaments could lead to disk displacement, then chin straps on football and other helmets should be reconsidered as to whether they are safe. If pressure on the TMJ ligaments can lead to osteoarthritis of the TMJ, then forces that are used for orthodontic care of Angle’s Class III patients should be reconsidered.

The airway governs our ability to breathe and to achieve a restful, oxygenated, restorative night’s sleep, as well as to perform optimally during the day. Any temporomandibular joint or occlusal philosophy must address airway patency while managing pain and dysfunction, identifying contributing factors and alleviating perpetuating factors. The teeth are the last piece of the Airway Centric paradigm. The airway is the first, then joint and muscle and, lastly, the occlusion.
Any TMJ or occlusal philosophy must also include a nighttime component to address parafunction or bruxism because of the shearing forces to the joint\textsuperscript{12} and increased tension of the cervical and masticatory muscles. Sleep bruxism is classified as a parasomnia or stereotyped movement disorder\textsuperscript{16} with obstructive sleep apnea as a leading risk factor. Other etiologic factors are autonomic sympathetic cardiac activation, sleep arousal, neurochemicals, comorbidities (SDB) and psychosocial factors.

SDB, defined as mouth breathing, snoring, upper airway resistance syndrome (UARS), hypopnea and apnea, leads to sleep fragmentation and decreased stage-three restorative sleep. Decreased stage-three, or delta slow wave, sleep has been linked to fibromyalgia\textsuperscript{17} and increased chronic pain.

Any TMJ or occlusal philosophy must address airway patency while managing pain and dysfunction, identifying contributing factors\textsuperscript{18,19} and alleviating perpetuating factors. The teeth are the last piece of the AC paradigm. The airway is the first, followed by joint and muscle and, lastly, the occlusion and anatomy of the teeth. Prevention of temporomandibular disorders (TMD), malocclusion and neurobehavioral and neurocognitive issues\textsuperscript{6} is the goal of AC TMJ philosophy and requires early identification and early intervention, although intervention can occur at any age.

**History of Centric Relation Dentistry**

My introduction to centric relation and the TMJ dates back to 1965 when I viewed the images my father, Harold Gelb, DDS, used for his lectures. It is now 49 years later, and the Gelb 4/7 position (FIGURE 3) has serendipitously evolved into the AC philosophy and the Gelb 4/7 Bite, Balance, Breathing method.

A little more history: In 1930 the fathers of gnathology, Harvey Stallard, PhD, DDS, Charles Stuart, DDS, and Beverly B. McCollum, DDS, followed Bonwill’s mechanical occlusion theory\textsuperscript{20} and translated the movement of the jaw to an articulator. The gnathologists developed a jaw position called centric relation (CR), which is the most retruded superior position of the joint (FIGURE 4). Some dentists referred to this jaw position as rearmost, uppermost or terminal hinge. The focus at that time was on the teeth and the occlusion and the way the teeth fit together and contacted in right and left lateral excursions. Other articulators were developed to support occlusal philosophies over the next 80 years, and include the Artex, Sam, Panadent, Whip Mix and Denar.

These gnathologists were revered and were inducted into the USC Dental Hall of Fame. Around the same time, Charles H. Tweed, DDS, had just graduated from Angle’s School of Orthodontics and rejected nonextraction theory as producing faces that were too protrusive.\textsuperscript{21} He began extracting permanent bicuspids to “flatten” profiles and supposedly give more stable results (FIGURE 5). Ron Roth, DDS, and Robert Williams, MS,\textsuperscript{22} applied the CR concept to orthodontics in ensuing years. Over the next 40 years, the gnathologists and Tweed orthodontists contributed to a more retruded jaw position with fewer teeth (FIGURE 5). This jaw position was taught and utilized in American dentistry from 1930-1995 and is still taught in some parts of the country.

To dentists such as Bill Farrar, DDS, Barney Jankelson, DDS, and Harold Gelb, this made no sense. The condyle wars in the 1970s pitted gnathologists such as L.D. Pankey, DDS, Peter E. Dawson, DDS, and the Society of Occlusal Studies against Gelb, Farrar, Jankelson and John Witzig, DDS. Witzig taught the European school of functional orthodontics popularized by Laszlo Schwartz, DDS, and Christine Frankel, DDS, which used the Gelb 4/7 position in nonextraction expansive orthodontics. Witzig was the expert witness in a landmark legal case involving a four-bicuspid extraction patient who required TMJ surgery following extraction orthodontics. The patient received more than $1 million, a substantial settlement at the time.

In the 1980s Dawson, along with the authors of the glossary of prosthodontic terms,\textsuperscript{23} realized that the gnathologists had no biologic or physiologic evidence for a retruded centric position. They followed Gelb, but with a more conservative anterior-superior position (FIGURE 6).
Celenza coined the term “long centric” after patients returned with their habitual comfort bites forward of the artificially retracted CR. Most prosthodontists and orthodontists still follow the “old” centric relation (FIGURE 4).

Psychophysio logically oriented Dr. Schwartz popularized the myofascial approach to TMJ treatment at Columbia University in the 1950s, and Daniel Laskin, DDS, and Charles Greene, DDS, then advanced their theory of myofascial pain dysfunction at the University of Illinois in 1969. Working with arthrography in the 1980s, Farrar and W.L. McCarty, DDS, in Montgomery, Ala., began to understand the workings of the TMJ disk. Further TMJ magnetic resonance imaging (MRI) research by Per-Lennart Westesson, DDS, and R.W. Katzberg, DDS, elucidated normal and pathologic movements of the condyle disk fossa assembly. Farrar believed that TMJ internal derangement produced myofascial pain.

Controversy continued as neuromuscular dentists concentrated on muscles while surgeons and other TMJ dentists focused on internal derangements of the TMJ. Teflon proplast TMJ implants were a disaster, but there was moderate success with TMJ arthroscopy and arthrocentesis.

The triad approach of muscle-joint-teeth, which considered myofascial pain and trigger points as well as TMJ internal derangements, became popular in the 1990s and was taught by Henri Gremillion, DDS, and Noshir Mehta, DDS, among others. It emphasized diagnosing joint and muscle pathology before looking at the occlusion.

Biopsychosocial research and theory published in the 1990s used research diagnostic criteria (RDC) from University of Washington faculty members Samuel Dworkin, DDS, PhD, Linda LeResche, ScD, and Edmond Truelove, DDS, MSD. The neuroscience group of the American Association for Dental Research (AADR) and the International Association for Dental Research (IADR) supported this philosophy and proposed reversible nonocclusal therapy, viewing oral appliances as unnecessary and mercenary. Unfortunately, most biopsychosocial researchers were not clinicians familiar with objective measurements found in polysomnograms (PSG) during sleep or with clinical pain management other than cognitive behavioral therapy.

AC TMJ Anterior Repositioning Therapy

Dr. Harold Gelb first described his mandibular orthopedic repositioning appliance in 1959 by placing the condyle in the Gelb 4/7 position within the glenoid fossa, slightly forward of concentric and against the eminence. This orthopedic technique was intended to three-dimensionally reposition the mandible in harmony with the neck, back and feet. Relatively decompressing the auriculotemporal nerve and TMJ could improve clicking, locking and shearing forces. According to Craniofacial Pain: A Handbook for Assessment, Diagnosis and Management from the Academy of Craniofacial Pain, “There is now a consensus opinion that the Gelb 4/7 position correlates with the physiologic normal position for the TMJ condyle in the fossa.” Farrar and McCarty advocated a position similar to that of Gelb and Ireland.

Positioning the mandible anteriorly using orthopedic repositioning has been shown to be efficacious for treating anteriorly displaced disks and to be superior to stabilization appliances or neuromuscular splints for relieving pain and dysfunction.

Before AC TMJ philosophy (FIGURE 2) was developed, the Gelb concept of three-dimensionally repositioning the mandible to reestablish a normal disk condyle position, while establishing normal resting lengths of the masticatory muscles, was the most effective method of treating internal derangements of the TMJ and the accompanying pain and dysfunction.

Recapturing of the disk with anterior repositioning occurred in 52 percent to 70 percent of patients in two early studies and 86 percent in a more recent publication. H. Clifton Simmons, DDS, and S.J. Gibbs, DDS, showed recapture in 25/26 joints, or 96 percent, using MRI before and after appliance therapy. Bite position for recapture was established using the Gelb 4/7 position, which represents a consensus of normal position of the condyles in the glenoid fossa.

While Harold Gelb continued to use the Gelb appliance, in 1989 the author, as director of the TMJ and Orofacial Pain Program at New York University, began using the NYU appliance, a modified
mandibular orthopedic repositioning appliance (MORA) (Figure 7). The NYU appliance covered the cuspids, which prevented intrusion and allowed for cuspid guidance, and placed acrylic around the linguals of the lower anteriors for stability. Both appliances worked best with occlusal indexing, which defined the new occlusion and gave increased proprioception while swallowing. Gelb and Gelb recommended a Farrar antiretrusion appliance at night for those patients with clicking or intermittent locking.43 Farrar27 utilized a position very similar to the Gelb 4/7 in accordance with arthrography to reposition the jaw and maintain that position at night with the Farrar antiretrusion appliance.27 Not only did Farrar prevent jaw clicking and locking during sleep, he, along with Gelb, serendipitously fabricated the first oral sleep appliances. When the mandible retracts to a retrognathic, or slack-jawed, position during supine sleep, the tongue and soft palate also retrace and collapse the airway. Nightguards traditionally fabricated in a terminal hinge-retruded position would also retrace the tongue and palate and lead to a collapsed airway. Gelb and Farrar were the first to go against the grain and maintain a forward position for an open airway during the day and at night.

Most of the TMJ/TMD research of the last 30 years has been measuring the wrong variables. With the advent of PSGs we can easily measure electrical activity of the heart with an electrocardiogram (EKG), electrical activity along the scalp with electroencephalography (EEG), electrical activity produced by muscles with electromyography (EMG), heart rate variability (HRV), CO₂ and O₂ saturation, as well as apnea, hypopnea, upper airway respiratory symptoms, arousals of the brain and body position with sound and video.

I propose that these objective physiologic measurements have already shown the efficacy of mandibular positioning appliances over the last 20 years, with multiple position papers published by physicians, sleep specialists and researchers.44 Sleep deprivation and SDB have profound effects on stage-three restorative sleep, which is necessary for repair and regeneration of musculoskeletal tissue, as well as on rapid eye movement (REM) sleep that is needed for well-being and memory consolidation. SDB also profoundly affects tissue inflammation, hypoxia and reperfusion, oxidative stress and endothelial dysfunction, all of which impact the TMJ, muscles of mastication and general well-being of the patient.

AC philosophy takes dentistry into the field of medicine and empowers the dentist or physician to treat apnea, hypopnea, upper airway resistance syndrome and snoring and, in doing so, to improve overall health and wellness. AC TMJ is a new philosophy in dentistry. The airway now trumps everything else in dentistry or medicine. Along with sleep and breathing, the airway is hierarchically the most important function for humans. Ideal health, wellness and brain development depend on an open pharyngeal airway, nasal breathing and restorative sleep. This requires a partnership between the ENT, pulmonologist, lactation consultant, myofunctional therapist,
obstetrician/gynecologist, osteopath, chiropractor and physical therapist.

The AC Bite, Balance, Breathing system recognizes these components and builds on the Gelb 4/7 position to establish an AC treatment philosophy so that dentists can recognize, diagnose and treat airway, breathing and sleep disorders to increase oxygenation and improve sleep architecture.

The AC team is an interdisciplinary collaboration of practitioners who integrate the airway, TMJ, masticatory and cervical muscles and teeth with growth and development as well as brain development, cardiovascular health, and treatment of diabetes, obesity and other chronic disease.

The airway includes the nasal airway, tonsils, adenoids, tongue, soft palate, uvula and lingual tonsil down to the epiglottis. Airway resistance and blockage have been associated with oxidative stress, systemic inflammation, intermittent hypoxia and endothelial dysfunction.

Phylogeny, Ontogeny and Animal Models of the Airway

Todd Morgan, DMD, and John Remmers, MD,8 shed light on the origins of air breathing from the lungfish to modern amphibians up to mammals, where we see the appearance of a diaphragm. The single oropharynx of the amphibian is transformed into three cavities: the nasal cavity, the oral cavity and the pharynx in reptiles and mammals. The soft palate becomes more developed in mammals as it separates the nasal cavity from the oral cavity and pharynx. The epiglottis appears with the evolution of the mammalian pharynx.10 The hyoid and larynx migrate downward and the airway above the epiglottis becomes angulated during mammalian evolution. With sucking or breast-feeding in humans, the epiglottis mechanically locks in with the soft palate to allow simultaneous sucking, swallowing and nasal breathing. The overlap of the soft palate and epiglottis is unique to all suckling mammals, except humans, where the epiglottis descends between six months and 1 year of age.

Morgan and Remmers8 ask the question, “Walking, talking and breathing: what is the problem?” Our evolutionary pressures to be bipedal and speak influenced the development of the pharynx. Our success as Homo sapiens depended on our intellectual advancement; with the development of the brain came our ability to walk and stand upright and our speech and articulation.45 These three factors had major effects on our pharynx and ability to breathe while asleep. With the possible exception of the English bulldog, obstructive sleep apnea (OSA) is a uniquely human disease.

The length and flexibility of the pharynx required for human speech is what leaves it vulnerable to collapse while we are asleep. The vast neural network and mechanoreceptors, which protect the airway during wakefulness, seen as increased activity of the genioglossus muscle, is lost during SDB. Morgan8 speculates, “Three features of the pharynx allowed walking and talking but severely limited the ability to breathe during sleep. These are:

1. Severely angulated airflow path because of upright posture.
2. Lack of epiglottal lock because of epiglottis descent and laryngeal length.
3. Free-floating hyoid and loss of hyoidal strutting. In all other mammalian species, the hyoid is firmly attached to the laryngeal skeleton. The descent of the hyoid from the mandibular plane predisposes for OSA.”

One of the most important changes in human primates is the shortening of the horizontal oral length and the relative lengthening of the vertical pharyngeal height. This change has a major impact on the AC TMJ and occlusal philosophy, as the maxilla has moved retrusively through evolution and epigenetic factors.46-48

Changes in the Maxilla – the Key

As humans evolved to an upright posture, the larynx descended,49 the forebrain grew and the facial framework retreated as the nasal airway became diminished in size and function. This is one reason humans do not have the olfactory ability of other mammals. As the cranial base angle flexed, the maxilla was compressed and the paranasal sinus size was reduced, creating millions of sinus sufferers, as well as other facial changes.

The flattened maxilla and longer face are a relatively recent human phenomenon, which differentiates us from primates. The decrease in nose volume associated with cranial base flexing may have increased high upper airway resistance and potential for collapse.
further down in the oropharynx. Humans were no longer obligate nose breathers, and with increased demands, mouth breathing was born. This trend of mouth breathing, downward migration of the tongue base and descent of the hyoid is associated with changes in mandibular posture to retrognathic. The increase in mouth breathing is also associated with less time spent with the tongue to the palate, narrowing of the maxilla and increased facial height. The downward and backward rotation of the maxilla and mandible is a powerful predictor of SDB as well as TMJ and malocclusion. A variety of researchers, clinicians and anthropologists has identified an underdeveloped maxilla as the root cause of malocclusion and naso-oropharyngeal constriction. Identification of mouth breathing is therefore recommended as early as the first year of life.

The animal model of OSA is the English bulldog that suffers from brachiocephalic syndrome. Since the 1950s the bulldog has been bred with a thicker neck and pushed-in snout. This brachiocephalic “retropositioning” results in a retruded maxilla and mandible similar to the description of human evolution above. This bony malformation reduces oral volume and pharyngeal space. The bulldog often exhibits pseudo class-three occlusion, crowded teeth, pinched nostrils and a large tongue that protrudes from the mouth. Most bulldogs expire from heart disease or cancer secondary to the effects of brachiocephalic airway narrowing and subsequent systemic inflammation, oxidative stress and hypoxia.

Egil Harvold, DDS, converted rhesus monkeys to mouth breathers by obstructing nasal breathing and observed increased face height, posterior rotation of the mandible and malocclusion. In growing animals in which the nasal airway is gradually occluded there is an adverse effect on the size of the nasomaxillary complex, mandible and pharyngeal air space. The same changes are seen in children who display habitual mouth breathing and who are at risk of SDB. Harvold stated, “Elimination of nasal airway interferences followed by changes from oral to nasal respiration may result in improvement of certain aspects of facial and dental deviations.”

A key aspect of the AC TMJ occlusal philosophy is, therefore, establishment of nasal breathing with ideal development of the maxilla.

**The downward and backward rotation of the maxilla and mandible is a powerful predictor of SDB as well as TMJ and malocclusion.**

### AC in Children

Pediatric sleep disorders result in disrupted, inefficient and inadequate sleep and may affect brain development and cause neuronal damage. Even habitual snoring is an indicator of a number of health problems in children, including poor physical growth, emotional and behavioral problems, neurocognitive impairment and decreased academic performance.

It is accepted that an apnea–hypopnea index (AHI) greater than 1 is abnormal in a child. Nasal airway obstruction is particularly significant in infants and young children who are obligate nose breathers. Many premature infants are born with high narrow palates and are mouth breathers from birth. These children also display orofacial hypotonia and secondary changes in maxillomandibular growth. Other children develop difficulty with nasal breathing when tonsils and adenoids develop between ages 2 and 8, which leads to chronic mouth breathing and SDB. Parents may report noisy breathing in infants rather than frank snoring. Bonuck found habitual snoring in 9.6 percent to 21.2 percent of children six months to 6.75 years of age. At age 6, 27 percent were habitual mouth breathers. Snoring increased significantly between 1.5 and 2.5 years in a study of 11,000 children older than 6 years. SDB causes abnormal oxygen and CO₂ levels, interferes with restorative sleep and disrupts cellular and chemical homeostasis. The fragmentation of stage-three restorative slow-wave brain activity by disruptive sleep or hypoxia can result in issues with decision-making, ambition and emotional regulation.

The AC TMJ philosophy starts prenatally with the mother’s nutrition and airway. Our goal is for a full-term pregnancy with ideal development of the palate and maxilla. At birth, we advocate for at least two months of breast-feeding, and preferably six months or a year if practical. This confers a reduction in SDB. A poor suck may result from hypotonia from birth and result in SDB.

Frenum attachments may need to be surgically released if they interfere with tongue movement or breast-feeding. Nasal breathing is of paramount importance for growth and development. If a child has nasal obstruction due to allergy, it must be addressed as early as possible.

Many premature infants are born with high narrow maxillas, which predispose them to mouth breathing, the first sign of an airway disorder. With mouth breathing, the tongue cannot assume proper rest posture against the premaxilla, resulting in
narrow, constricted, high-vaulted palates and poor maxillary growth. It can also result in a poorly developed nasal airway, increased facial height, a retrognathic mandible, shorter maxilla and mandible, larger tongue, longer and thicker soft palate and an inferiorly placed hyoid bone.

Tonsils and adenoids tend to hypertrophy between ages 2 and 8; however, before that, by six, 18 and 30 months of age, snoring and sleep apnea are already present, which predict neurobehavioral disorders at age 4 and 7. Children in one study who were symptomatic in infancy were 20 to 60 percent more apt to exhibit neurobehavioral disorders by age 4, and 40 to 100 percent more likely by age 7. Symptoms included hyperactivity, misconduct and peer difficulties. These attention and executive function deficits persisted into adulthood.19

Early SDB may lead to permanent prefrontal cortex change, causing attention and executive function problems even if the SDB improves. In other words, SDB’s effects may be irreversible.6

Our knowledge of brain changes encourages intervention as early as the first year of age. The trend today is adentotonsillectomy (AT), palatal expansion and myofunctional therapy as early as age 3.5. AT resolved only 51 percent of OSA in nonobese prepubertal children.1 Children who snore in early childhood tend to have lower academic performance independent of AT later in development.19 History of either SDB or behavioral sleep problems in the first five years led to increased likelihood of special educational need at age 8 in one study.19

The maxilla can be developed very early in childhood and has a huge impact on improving nasal breathing and SDB. Narrow maxillas also predispose to TMJ disorders, growth abnormalities and SDB. Sixty percent of facial growth is attained by age 6 and 90 percent by age 11 or 12; therefore, early intervention is particularly warranted in children with SDB. Occupational therapy and myofunctional therapy with special orofacial exercises during feeding and chewing in the first two years of life may lead to improvement in facial anatomy, repositioning of the tongue and development of a normal nasomaxillary complex and mandible.10

The maxilla can be developed very early in childhood and has a huge impact on improving nasal breathing and SDB.

It is encouraging to realize that early interdisciplinary intervention may prevent SDB and subsequent pathologic sequelae.

Development of the Maxilla

Epigenetic factors are thought to have dramatically changed the development of the jaws.52 Robert Corrucini, PhD, has also attributed crowded teeth and small, narrow jaws to the soft consistency of the diet. Kevin Boyd, DDS, a pediatric dentist, points to the dietary changes following the industrial revolution and lack of breast-feeding as a cause for the shrinkage of the maxilla.7

Seminal work by Weston Price, DDS, has demonstrated that malocclusion occurred in primitive tribes within two generations of the introduction of an industrialized diet.60

Most jaws today do not have room for all 32 teeth, as evidenced by the number of children and young adults who require wisdom teeth extractions. Comparing the wide U-shaped skulls from the Smithsonian and the Museum of Natural History with today’s skulls indicates that the maxilla has significantly retracted.

Epigenetic factors include environmental pollutants, obesogens, sugar in our diet and pesticides. These factors are also thought to have caused the sudden dramatic increase in attention deficit hyperactive disorder (ADHD), obesity, diabetes, heart disease and a spectrum of other disorders.

Abnormal nasomaxillary growth is thought to be responsible for SDB and TMD. AC philosophy addresses the following vital pathologic processes:

- Oxidative stress — results in free radical production.
- Systemic inflammation — associated with the release of inflammatory cytokines, tumor necrosis factor alpha (TNF-alpha), interleukin 6 (IL6).
- Intermittent hypoxia — oxygen desaturation is followed by reperfusion, often hundreds of times per night.
- Endothelial dysfunction — reflects the health of the blood vessel wall and the ability to vasodilate. It is the risk factor of risk factors for cardiovascular disease.
- Autonomic deregulation — thought to be a major contributing factor in the development of cancer and cardiovascular disease.

Lack of quality sleep increases pain and lowers immune function while increasing TNF-alpha, IL6 and interleukin 8 (IL8).61

Most chronic diseases are greatly influenced by the airway and breathing. Opening the airway with the AC TMJ philosophy allows normalization of endothelial dysfunction and reduces oxidative stress, systemic inflammation and intermittent hypoxia. This is often
the missing link for the treatment of fatigue, obesity, ADHD, diabetes and cardiovascular disease.

AC treatment will help determine the final TMJ, muscle and occlusal position. The TMJ will be decompressed and the pharyngeal airway will be open.

**Nighttime Philosophy**

Therapeutic jaw position at night is dictated by the airway first and TMJ second. Because bruxism is associated with brain arousal and is thought to be related to SDB, a sleep study is required for any patient with excessive daytime sleepiness (EDS), snoring, witnessed apnea, high blood pressure (HBP) or narrowed airway. Home sleep studies or PSG are both adequate, depending on comorbidities and the information required.

A positive sleep study will usually necessitate an oral appliance to maintain an open airway, sometimes combined with continuous positive airway pressure (CPAP), nasal surgery and positional therapy. Treatment duration could be three to six months followed by a sleep study to ensure efficacy.

Bite changes can be expected, particularly for patients with class-two division-two malocclusions or retruded maxillas. At a three-week follow-up visit, the dentist monitors the list of chief complaints related to pain and dysfunction. Criteria for success require alleviation of pain and dysfunction complaints as well as of EDS, noisy breathing and OSA.

**Daytime Philosophy**

Oral appliances are often used during the day as well to address daytime complaints, which require habit control and TMJ or muscle rehabilitation, particularly for patients who need cognitive behavioral therapy. Many patients who present with SDB also have headache and dysfunction related to growth and development, parafunction or past trauma. In patients who present with TMD, pain or dysfunction, the appropriate appliance design is chosen in combination with physical therapy, medication, Botox injections, craniosacral therapy, chiropractic or osteopathic manipulation. Lower appliances are preferred during the day to help articulation. The NYU and lower stabilization appliances are recommended for six to 12 weeks of daytime wear and then as needed during physically and emotionally stressed periods. These might include exercising, playing competitive sports, studying for and taking tests, and putting in intense days at work.

**Vertical Dimension**

Most patients have lost vertical dimension or have compressed temporomandibular joints. In long-face patients, we want to decompress the joint without opening vertical more than necessary. In anterior open bites, we always establish anterior guidance by providing anterior contact.

In dental school, we were taught that one could not open the vertical dimension of occlusion. We now know that the body will reestablish freeway space, and often the vertical needs to be added to at night to maintain an open airway.

**Anterior Posterior**

Epigenetics has predisposed to predominantly retrognathic bites with forward head posture. As we reposition the mandible forward, we work with physical therapists who use the Alexander Technique, Feldenkrais Method, Pilates and Gyrotonics to strengthen the core and achieve ideal posture, like that of a dancer or actor.

As we bring the jaw forward, the head goes back over the shoulders. Our philosophy is to decompress the jaw joints bilaterally by anterior repositioning of the mandible. Criteria for repositioning include recapturing the disk when possible, alleviating joint noise when possible, achieving ideal facial esthetics, maintaining minimal bite opening during the day and maintaining natural anterior guidance when possible.

I tell my patients that I am putting their chins back to the middle of their faces. When phonetics and ramus height discrepancy support moving the mandible back to the center while alleviating joint compression and reducing joint noise, it is done. The mandible often migrates to the short ramus side, which is the high eye side.

**Beauty**

Nonsurgical facelifts were talked about in the ’80s and ’90s. Today we are able to restore full lips and reduce nasolabial folds, but more important, increase the oxygenation of the skin and open the eyes. There is a glow and sense of life that was missing. Part of the transformation is the reduction in pain and stress on the body. More important perhaps is the healing effect of restorative sleep, decreased inflammation, hypoxia and oxidative stress.

In approximately 10 percent of adult cases and 100 percent of children’s cases, orthodontics, such as palatal
expansion, is required. Smile lifts, as popularized by Larry Rosenthal, DDS, from NYU and Aesthetic Advantage, are often needed because of the preponderance of narrow maxillas. Dr. Rosenthal and I have restored several cases after TMJ and AC stabilization.

Occlusal Philosophy

Many patients have anterior open bites secondary to condylar degeneration or perimenopausal changes in the joint. In those cases, we always establish anterior guidance, typically bringing the mandible forward to decompress the joint and open the airway. Whenever possible, the appliance establishes canine guidance. I use a modified Gelb appliance for daytime, covering the cuspids and placing acrylic behind the lower anterior teeth to prevent shifting.

Gnathologic principles can be used if the jaw is in the right position.

Slight posterior open bites are acceptable and often preferred. We want the majority of force in the premolars and anterior teeth. A slight posterior open bite discourages parafunction.

In 10 percent of cases, some form of dentistry is required following my treatment plan, which often involves physical therapy, trigger point injections and Botox injections.

Criteria for Success

Airway

- Open day and night.
- Improved SDB or AHI; respiratory disturbance index (RDI) decreased by at least 50 percent.
- Improved EDS.
- Nasal breathing.

Posture (standing, seated and supine)

- String pulling up the back of the head with slight flexion.
- Normal spinal curvature achieved with Alexander Technique, Feldenkrais Method, Pilates, yoga.
- Lips together, teeth apart.
- Chest up.
- Belly in, engage abdominals.

TMJ

- Absence of clicking, popping, locking.
- Decompressed in the range concentric to Gelb 4/7.
- Full range of motion or a measured opening of 36-54 mm.

Face

- Shape — favors horizontal growth.
- Lips — full and symmetrical.
- Skin tone — glowing.
- Eyes — open and alive, not showing too much sclera.
- Profile — good vertical and strong lower jaw.

Teeth

- Smile lift or palatal expansion to fill buccal corridors.
- Support airway and TMJ.
- Cuspid rise.
- Anterior coupling.
- OK to have lighter contact posteriorly or slight posterior open bite.

Conclusion

A small upper airway and stunted nasomaxillary complex predispose humans to SDB. Early intervention is essential to prevent and correct anatomic abnormalities, which will also prevent SDB and resultant emotional and behavioral problems, neurocognitive impairment, decreased academic performance and poor physical growth. SDB has also been associated with hypoxia, oxidative stress, disrupted sleep and endothelial dysfunction, all precursors to obesity, cardiovascular disease and diabetes.

Upper airway resistance and SDB are also linked to a retruded short maxilla and retrognathic mandible, which predispose to TMD headache and cervical postural change.

The Airway Centric TMJ and occlusal philosophy will result in a condylar position between concentric and Gelb 4/7 during the day and Gelb 4/7 to the middle of the eminence at night.

Robert M. Ricketts, DDS, stated, “Respiration and mastication are biologically inseparable. It would appear that normal nasal breathing is conducive to normal growth of the maxilla and normal development of the occlusion of the teeth.” The influence of gnathology and orthodontics in the 30s and 40s led to the concept of treating just the teeth instead of the face or the patient as a whole.

Ricketts also wrote, “We talk about the oral cavity as if it is independent of the development of the first branchial arch and independent from respiration. Biologically, the functions of mastication and respiration have been connected with the same set of muscles and the same set of nerve paths. We can’t separate them.”

Final occlusal restorations cannot be completed until SDB is successfully managed over a six-month to one-year period. There will be occlusal changes based upon the initial position of the nasomaxillary complex, mandible, pharyngeal air space, hyoid bone and craniofacial morphology.

The dentist should recognize and address TMJ and airway disorders prior to restorative dentistry, as TMJ and airway treatment may result in occlusal changes.

Other Authors’ Critiques of Dr. Gelb’s Paper

Dr. Simmons

Dr. Gelb’s manuscript is an excellent review of the relationship between TMDs and sleep-disordered breathing (SDB). His thought process involves evaluating patients who needs TMD care for SDB. This is an appropriate process.

The term temporomandibular disorders should be used only as a general statement to describe all disorders that can affect the temporomandibular complex. TMDs include all TMJ internal derangement disorders, arthritic disorders and fractures and all associated structure muscle disorders, nerve disorders, vascular disorders, neoplasms and genetic disorders. Specific disorders of the TMD complex should be referenced when treatment methods are described.

Intracapsular TMDs are usually not preventable because most are a result of TMJ articular disk displacement secondary to ligament injury. The orthopedic medicine community clearly believes that acute macrotrauma is the cause of most ligament injuries. Acute macrotrauma may not be preventable.

Dental occlusion is driven by many factors, among which are genetics, the tongue, the cheek muscles, dental diseases and the airway.

TMJ/TMD research measures appropriate variables, such as range of motion, pain upon anatomic site palpation, etc., but it is also appropriate to measure SDB variables in this patient population.

Slight posterior open bites are an acceptable result of reversible anterior repositioning appliance care but should be closed by either a long-term appliance, orthodontics or other restorative method. The reviewing author does not believe that most dentists would prefer a posterior open bite occlusion or that this status of occlusion discourages parafunction.

Not all TMD patients need airway care. A significant number of TMJ internal derangement patients have airway issues and need care for this disorder. The treatment concepts presented in this manuscript are valid.

I would like to thank Dr. Gelb for participating in this journalistic endeavor. His patients appreciate his care in relieving their pain and dysfunction and their airway needs.

Dr. Gelb’s Response to Critiques

Response to Dr. Fricton’s critique

Dr. Fricton introduces the dental community to a human systems approach for chronic pain and temporomandibular disorders. I would like to thank Dr. Fricton for a novel and thought-provoking manuscript.

Response to Dr. Simmons’ critique

I would like to thank Dr. Simmons for an excellent manuscript. In those TMJ patients who do not have resistive breathing or sleep disordered breathing, I would follow Dr. Simmons’ TMJ philosophy.

Response to Dr. Raman’s critique

I agree that Airway Centric (AC) TMJ philosophy is often congruent with a neuromuscular (NM) approach, as both open the airway and relatively decompress the joint.

Following six months to one year of AC appliance therapy, the mandible will usually reach a stable and repeatable down and forward position during the day with the appliance out. This position is taken only after a polysomnogram or home sleep test has confirmed successful treatment of sleep disordered breathing.

The NM approach does not ensure successful TMJ or airway management. It measures electromyography (EMG) and computer mandibular scanning. Some AC dentists measure real-time heart rate variability (HRV) to fine-tune appliance and jaw position.

AC moves beyond Gelb 4/7 condyle repositioning therapy by placing an open airway hierarchically at the top of the pyramid.

Final treatment position should optimize HRV, EMG and resonant frequency breathing. Final treatment position maximizes oxygen saturation, stage three and REM sleep and manages the apnea–hypopnea index (AHI), respiratory disturbance index (RDI) and sleep fragmentation and arousals.
Physiologic Neuromuscular Dental Paradigm for the Diagnosis and Treatment of Temporomandibular Disorders

Prabu Raman, DDS, MICCMO, LVIM, FPFA, FACD

ABSTRACT Shifting from traditional anatomical/mechanistic models, the physiologic neuromuscular dentistry (PNMD) paradigm acknowledges the primacy of physiology in shaping and controlling anatomy in a functioning human body. Occlusal disharmony from mandibular discrepancy to cranium leads to temporomandibular disorders (TMD), which is a disease of musculoskeletal imbalance in the postural chain exceeding the individual’s physiologic adaptive capacity. To diagnose optimal craniomandibular alignment, PNMD is guided by real-time objective physiologic data such as electromyography (EMG).

AUTHOR

Prabu Raman, DDS, MICCMO, LVIM, FPFA, FACD, has practiced dentistry in Kansas City, Mo., since 1983, with an emphasis on neuromuscular dentistry/temporomandibular dysfunction, esthetic dentistry, complex restorative dentistry, neuromuscular functional orthodontics and sleep breathing disorders/oral appliance therapy. He is a fellow of the American College of Dentists and a fellow of the Pierre Fauchard Academy. Dr. Raman is a past president of the International Association of Comprehensive Aesthetics, a past president of the Greater Kansas City Dental Society and serves as an HOD delegate, member of the Council on Dental Education and Licensure of the American Dental Association and as a trustee of the Missouri Dental Association. He earned his dental degree from the University of Missouri, Kansas City, School of Dentistry.

Conflict of Interest Disclosure: None reported.

The diagnosis and treatment of temporomandibular disorders (TMD) is the most confusing subject in dentistry. Many factors contribute to this confusion; chief among them is a simplistic view of this disease that relates it only to temporomandibular joints (TMJs) or attributes it to a single etiology. Another factor is the lack of TMD training in predoctoral dental education.

TMD encompasses a group of musculoskeletal and neuromuscular conditions that involve the masticatory system, the dentition (occlusion), the TMJs and all associated tissues. Quantum improvements occur in any arena with a change in the basic paradigm. The physiologic neuromuscular dentistry (PNMD) paradigm offers such a significant improvement in how the dental profession views and treats TMD. It acknowledges the primacy of physiology in shaping and controlling anatomy in a functioning human body. A guiding principle of PNMD is, “If it has been measured, it is a fact. If it has not been measured, it is an opinion.” As such, physiologic data such as electromyography (EMG) of the jaw and neck muscles drive diagnostic and clinical decisions.

Video for this article is available in the e-pub version of the Journal, available at cda.org/apps.
The concepts and practice of neuromuscular dentistry go back to the 1950s and have since been improved considerably. These concepts are based on principles of physiology that earned Nobel prizes for their discoverers — Hill (glycolysis), Sherrington (reciprocal inhibition), Krebs (adenosine triphosphate [ATP] production), Eccles, Hodgkin and Huxley (action potential, myoneural junction, sliding muscle filaments) and Katz (muscle frequency and fatigue). Yet, many in our dental profession are still unfamiliar with PNMD concepts.

A dentist’s duty is to relieve pain or adverse symptoms from which a patient seeks relief. Our patients are best served when TMD is viewed more comprehensively as a disease of musculoskeletal imbalance in the postural chain exceeding the individual’s physiologic adaptive capacity. This paradigm is more useful in the diagnosis and definitive treatment. Cranio-cervico mandibular disorder (CCMD) would be a more accurate description of this disorder, but due to the historic use of the term, “TMD” is used in this paper.

Symptoms of TMD are so varied that it has been called the “great impostor.” They include orofacial symptoms such as TMJ pain, articular disk displacement without reduction (closed lock), articular disk displacement with reduction (clicking) with or without pain, limited mandibular range of motion, facial pain, referred dental pain, excessive tooth structure loss, unexplained tooth mobility, unexplained bone loss and more. TMD symptoms also include headache, migraine,1 earache,2 ear congestion,4 autophony, tinnitus,7 vertigo,8 cervical pain,9 limited cervical range of motion, forward neck posture,10,11 obstructive sleep disordered breathing,12 fibromyalgia, swallowing disorders,13 arm pain, paresthesia of fingertips,13 back pain13 and more. Other disorders of the body can cause some of the same symptoms, so a differential diagnosis must include TMD as a possible etiology, and other pathologies must be ruled out through appropriate tests or referrals.

The role of occlusion in the etiology of TMD has been widely documented in the dental literature.14 Occlusal disharmony can result in hyperactivity and a disturbed pattern of muscle contractions leading to muscular pain and joint overload.15 Palpation alone is a gross indicator at best and is subject to highly variable results among clinicians and to variability in the patient’s tolerance. Therefore, palpation alone is inadequate to provide the best possible clinical evaluation of the masticatory muscles.16 Would we use subjective pain reported by a patient as the only criterion to evaluate the health of periodontium or of a carious lesion? A scientific and objective assessment of the masticatory muscles as part of the clinical examination is essential. Numerous studies have shown that the TMD patient population has elevated resting EMG activity and weak or asymmetrical functional EMG activity.12,19 TMD patients frequently exhibit altered muscle activation patterns.
The role of dentition is unique in the postural chain. No other joint has the end point that is as changeable as the dentition is to the TM joints. While much emphasis is placed on the actual interdigitation of teeth (occlusion), the effort needed by the mandibular posturing muscles to bring the teeth into occlusion is not usually measured. No matter how poorly aligned the teeth might be, the masticatory muscles will bring the teeth into occlusion so that we may chew, eat, swallow and survive. For example, if a poorly aligned door runs into the doorframe, it can still be forced to shut; but over time, this would lead to deterioration of the hinges. While no one will consider only the shut position of such a door and pronounce it as perfectly fitting, looking at the final occlusion alone ignores the muscular effort required to bring the mandible into that position. In this analogy, would the deterioration of the hinges be the only condition to qualify it as a problem? This is akin to those who would not consider a patient to have TMD if there are no overt signs of TMJ internal derangement or other joint symptoms. This analogy does not at all convey the complexity of the stomatognathic system.

Mandibular position and occlusion have a profound effect on postural stability.\(^{20,21}\) Swallowing occurs hundreds of times a day.\(^{22}\) When teeth contact, as in swallowing and chewing, mechanoreceptors in the periodontal ligaments are stimulated. These serve as an important peripheral afferent of proprioception for the central nervous system.\(^{23}\) Forty percent of the postural data that the brain receives is from the position of the mandible in space.\(^{24}\) Mandibular posture and cervical posture are functionally connected;\(^{25,26}\) as such, mandibular posture affects upper cervical posture.\(^{27,28}\) The alignment of these craniovertebral cone superstructures also affects the lumen of the spinal canal at this critical level, as well as the flow characteristics through the vertebral arteries. It even impacts the tension on the recently discovered myodural junction between dura mater and the rectus capitus posterior minor muscle,\(^{29}\) which could explain cervicogenic headaches. TMJs are functionally related to the atlanto-occipital joints,\(^{30}\) which in turn have a profound impact on the central nervous system.\(^{31}\) Cervical posture affects the lumbar and overall posture.\(^{32}\) Based on these facts, it is clear that the impact of dental occlusion on the function of the human body is quite profound.

TMD sufferers do not want to be medicated for the rest of their lives to only dull their symptoms through a medical pain management paradigm. Many consider these medications to be ineffective or the side effects unacceptable. Most find their condition progressing from mild to worse and sometimes to disabling. While they experience unrelenting pain or discomfort, many patients do not show radiological evidence of breakdown in their TMJs for years or show external signs such as hemorrhage or edema. This is a helpless position to be in, to feel the pain but see no end in sight. However, EMG studies are valuable in objectively revealing the dysfunctional physiology of the masticatory muscles.

To illustrate this point, the author presents the case history of Dana P. After all, intellectual discussions of philosophical differences do not interest dentists in clinical practice as much as the application of such a philosophy in helping an actual patient. Dana, a 49-year-old female small business owner who was in good health except for a 15-year history of weekly migraines, presented for a TMD evaluation. Her general dentist, an oral surgeon who evaluated her TMJ and the orthodontist who treated her as an adult to achieve better occlusion had all concluded that she had no “TMJ disorder.” She had been diagnosed with migraines by a neurologist and had been on various migraine, nausea and muscle relaxant medications for maintenance and to abort migraines. Otolaryngologists, allergists, pain management specialists, three chiropractors, a physical therapist, four neurologists and numerous massage therapists had treated her over the 15 years. Yet she also had back pain, neck pain, pain behind the eyes, shoulder pain, etc. When she took Zomig to abort a migraine onset, she would have to lie down in a dark room for a day and it often took another day for her to feel normal again. Because she had two to three migraine attacks a week, most days she was either in bed with a migraine or recovering from one.

Oral examination of the hard and soft tissue was done. Findings were:
- Teeth Nos. 1, 5, 12, 16, 17, 21, 28 and 32 had been removed for orthodontia.
- Bilateral mandibular buccal exostoses, bilateral articular and mandibular notching and a scalloped tongue were noted.
- Mandibular range of motion:
  - vertical = 54 mm, right lateral excursion = 11 mm, left lateral excursion = 9 mm, protrusion = 10 mm.
- Upper cervical rotation range of motion was measured: 65 degrees to the right side, 60 degrees to the left side.
- Blood pressure: 122/77, pO2: 99% and pulse rate: 62 were...
recorded with pulse oximetry.

- Palpation of TMJ, jaw and cervical muscles was performed and recorded.
- Severe tenderness was noted at left shoulder trapezius and bilateral lateral pterygoids; moderate tenderness was noted at bilateral medial pterygoids, right posterior scalene and bilateral stylomandibular ligaments; mild tenderness was noted at left temporal tendon, right levator scapula, right neck trapezius, left posterior scalene, right anterior scalene, right sternocleidomastoid muscle (SCM), bilateral occipital, bilateral middle scalenes, bilateral posterior TMJ space and bilateral joint capsules.

Cone beam CT evaluation of the TMJs was within normal limits with slight reduction of joint space. It was negative for condylar deformation or deterioration (FIGURES 1 and 2).

A Myotronics K7 evaluation system was utilized. The patient’s resting EMG, shown on the left half of the image, was within the norms noted on the left margin. However, the effort it took for her temporalis muscles just to bring the teeth into occlusion, shown on the right half of the image, increased 5X on the left and 8X on the right side compared to resting posture (FIGURES 3 and 4).

Her cranial nerves V, VII and XII (trigeminal, facial and spinal accessory nerves) were pulsed for 60 minutes by ultra-low-frequency transcutaneous electroneural stimulation (ULF-TENS). Every muscle innervated by these nerves was pulsed for 0.5 second every 1.5 seconds so they would contract and relax, essentially massaging each of these muscles to improve oxygenated blood flow, eliminating waste products such as lactic acid from the muscles to reestablish a biochemical and physiologic optimum. A repeat EMG showed even lower recruitment of these muscles, denoting relaxed muscles. From this optimal physiologic condition, the true magnitude of the mandibular discrepancy was revealed when the patient brought her teeth into light occlusion requiring 7X on the right side and 12X on the left temporalis (FIGURES 5 and 6).

Once the 3-D relationship of the mandible to maxilla was diagnosed, a temporary anatomic fixed orthotic was constructed of Integrity resin (DENTSPLY, Milford, Del.) on the mandibular arch to allow for physiologic economy of the posturing muscles. The patient functioned with this fixed orthotic that she could not remove but that could be removed by the dentist if the treatment was unsuccessful in symptom resolution. At a follow-up visit seven days after delivery, the mandibular function was again objectively evaluated and coronoplastied. The same act of bringing the teeth into occlusion was almost effortless with the orthotic (FIGURES 7 and 8).

While this objective measure of improvement is encouraging, the most important measure is that all of Dana’s symptoms resolved 70 percent within 30 days, far exceeding her expectations. Therefore, she chose the option of orthodontically moving her teeth, guided by the physiologic metrics to permanently change her mandibular alignment. One year later, she is currently undergoing physiologic neuromuscular orthodontics and remains 90 percent symptom-free. The improvement in Dana’s quality of life and that of her family is immeasurable, according to her and her husband.

Dentists who choose to treat TMD patients should acknowledge that TMD is multifactorial. They should use objective measurements of physiology to supplement anatomical data such as radiographic imaging and subjective reports in the diagnosis and treatment. TMJ radiographic imaging does not make a diagnosis of etiology in and of itself. Qualified medical professionals interpret imaging records and those data facilitate the overall diagnosis. Similarly, surface EMG studies provide objective clinical information about masticatory muscle status, which a properly trained dentist interprets to aid in his or her...
diagnosis. The bioelectronic devices commonly known as neuromuscular measurement devices are used to provide the diagnosing clinician with much expanded, precise, objective measurements and clinical information to reach an accurate diagnosis. The role of these instruments in reliably documenting and providing objective data is well documented in numerous studies.38-40

As dentists, our training and license to practice limit us to the orofacial region. At the outset, it is necessary to determine whether the primary etiology of the patient’s complaints is related to a discrepancy of mandibular posture. If so, a comprehensive gathering of data is needed to facilitate an accurate diagnosis. These may include the following:

- Comprehensive history, including medical and dental history.
- Thorough examination of the dentition and periodontium.
- Diagnostic photographs of the dentition, face and posture.
- Palpation of the muscles of mastication, TMJs and cervical muscles.
- Range of motion records of mandible and upper cervical spine.41
- Surface electromyographic (sEMG) studies of muscles of mandibular and cervical posture.42 These may include sEMG measurements of muscles of mandibular posture at rest,43,44 with teeth in light habitual occlusion,45 maximum clenching46 and contraction frequency of muscles that indicate muscle fiber types and fatigue levels.47 The utility and reliability of sEMG is well established in research literature.48-50
- Computerized jaw tracking studies of mandibular movement.51
- Electrosongraphy (ESG) recordings of TMJ sounds during function.52
- Cone beam CT views or corrected tomograms of the TMJs in habitual occlusion, maximal opening and maximal protrusion.
- Static posture and gait analyses to identify postural compensations.
- ULF-TENS of muscles of mastication and cervical posture through neurally mediated pulses.53-57
- Determination of the physiologic neuromuscular mandibular position within a neutral zone when muscles of mastication and cervical posture are optimally unstrained.58 Objective, real-time EMG measurements of the posture muscles guide the clinician in diagnosing this position.59 There is universal agreement on comfortable, unstrained masticatory muscles as a requisite for a healthy stomatognathic system. PNMD protocols actually measure physiologic data to confirm this, rather than just relying on subjective measures. The discrepancy between the mandibular position of presenting habitual occlusion and the physiologic neuromuscular mandibular position is the starting point of therapy.60

A neuromuscular dental treatment plan requires minimal or no treatment when the dentist’s diagnosis so indicates. Provisional, reversible treatment that accommodates chewing and speaking is used first to confirm the efficacy of therapy, validate the planned treatment and to further refine the mandibular position before any permanent alteration of the teeth is done. Because mandibular posture is a function of the overall posture, as the posture improves, the mandibular posture may change as well until stability is achieved. The patient and dentist have the option of discontinuing orthotic therapy if there is inadequate improvement. Objective measures, similar to the pretreatment diagnostic series, are used to evaluate progress. Treatment progress needs to be evaluated partly through subjective reports, as has been done traditionally. However, because there are inherent inaccuracies involved in subjective reports, objective measures are needed, as well. This is akin to a physician using electrocardiogram recordings or blood pressure readings for diagnosis as well as evaluating the efficacy of treatment and not just relying on how the patient feels. Only when there is substantial improvement in both subjective and
dentist’s clinical expertise and the patient’s medical condition and history, with the evidence, relating to the patient’s oral and assessments of clinically relevant scientific the judicious integration of systematic conference, “Evidence-based dentistry is an placed on literature citations. As defined at the 2008 ADA Evidenced-based Dentistry (EBD), the greatest importance is accorded to evidence, including prior probabilities, as building blocks for new data. These prior probabilities may include the experience of having previously adhered to a specific scientific plausibility — or ‘prior probability’ — also must be considered. Good science accounts for all relevant evidence, including prior probabilities, as building blocks for new data. These prior probabilities may include the experience of having previously adhered to a specific treatment approach and … health care providers must continually seek to improve the quality of patient care through sound professional judgment based on provider experience, expertise and clinically relevant research.”

Neuromuscular dentists have the necessary expertise and the experience of thousands of patients whose TMD symptoms were successfully resolved through a comprehensive approach for evaluation and treatment. PNMD protocols are indeed guided by evidence-based dentistry in line with the ADA’s position of considering the clinical expertise of thousands of private-practice dentists around the world who successfully treat TMD patients daily. Even more important, this approach considers the treatment needs and preferences of patients who choose treatment options after being fully informed of the consequences of all options — including letting their disease continue without any intervention. All caring practitioners can support this approach that respects the patients who seek our care.

Other Authors’ Critiques of Dr. Raman’s Paper

Dr. Fricton

Physiologic Neuromuscular Dentistry Strategy. Dr. Raman discusses the use of objective physiologic data such as surface electromyography (EMG) and jaw tracking to determine whether occlusal disharmony is causing muscle hyperactivity in the masticatory system. To illustrate his point, he presents a case showing that muscle activity was reduced when a permanent full-time occlusal splint was used. At 30-day follow-up, 70 percent of the patient’s symptoms were resolved. Thus, he recommended that the patient redo her orthodontic care to move her teeth and jaw to a new “physiologic” position as determined by surface electromyography. The paper states that because this approach uses objective equipment such as EMG and jaw tracking, it follows evidence-based dentistry. Unfortunately, the paper does not review any scientific evidence related to the reliability and validity of these diagnostic tests nor the results of any placebo-controlled, randomized controlled trial evaluating the efficacy of this approach. Furthermore, the possible adverse events of this approach are not discussed.

Editor’s note: See Dr. Fricton’s general comments and conclusion on page 545.

Dr. Simmons

Dr. Raman’s manuscript is supportive of neuromuscular dentistry concepts. Muscle dysfunction concepts and management by transcutaneous electroneural stimulation (TENS) are described. A mandibular rest position is achieved and utilized as a dental occlusal treatment position for relief of pain and dysfunction of the masticatory muscles.

Page 563 “As such, physiologic data such as electromyography (EMG) of the jaw and neck muscles drive diagnostic and clinical decisions.”

Muscle pain, one of the symptoms associated with TMD, has not been shown to be consistently enough reflected in EMG data (J. Radke, president, BioResearch Inc., written communication, February 2011).1 Internal derangement of the TMJ does not universally alter muscle function in a predictable way such that EMG data can consistently detect this condition (J. Radke, president, BioResearch Inc., written communication, February 2011).1 TMJ surface EMG in clinical use has little value in testing for the presence or absence of specific masticatory muscle and TMJ disk displacement disorders.2-4 There is very little consensus about the use of EMG in the diagnosis and treatment of some TMDs.

Page 564. “So palpation is inadequate to provide the best possible clinical evaluation of the masticatory muscles.”

On page 565, Dr. Raman uses detailed palpation of TMJ, jaw and cervical muscles in his example of a patient examination. On page 567, Dr. Raman lists “Palpation of the muscles of mastication, TM joints and cervical muscles” in his gathering of data for a diagnosis.

Page 564. “TMD patients frequently exhibit altered muscle activation patterns.”

Muscles do cause most of the pain in a TMD patient, but the cause of the disorder is usually not the muscles; it is the underlying injury to the TMJ or neck vertebrae. Cyriax believes that muscles are the alarm that tells us there is something wrong in the neighborhood.5 The question that should be asked is, “Why are these muscles in involuntary contraction?” Isberg believes that chronic contraction in the muscles of mastication may be caused by a displaced TMJ disk.6 Cyriax believes that if one can treat the joint’s arthritis and/or internal derangement, the muscle contractions resolve on their own.7 Neuromuscular dentistry seems to be treating the secondary, not the primary, cause of a patient’s pain and dysfunction.
How does the neuromuscular dentist treat an acute disk displacement without reduction or intermittent acute displacement without reduction? If a practitioner is solely focused on the muscles, how is a TMJ internal derangement treated?

Care of the TMD patient is broken down into assessment, diagnosis and management. Diagnostic tests, beyond range of motion, anatomic site palpation and diagnostic anesthetic blocks, have a minimal role in determining who needs TMD care. The diagnosis of the TMD patient is properly based upon history (82 percent); then confidence in the diagnosis is added with examination (9 percent) and testing (9 percent).

This paper is supportive of neuromuscular dentistry as the method of diagnosing and treating TMDs. Any significant opening of the mouth through muscle pulsing with TENS or other method causes anterior repositioning of the mandibular condyles in their fossae. The reviewing author believes that this technique accomplished its goals because of the underlying repositioning of the condyles to a more physiologic orthopedic position in the fossae. This anterior repositioning of the condyles may have caused the muscles associated with the joint to sense that the joints were more normal and therefore the muscles to reduce in contraction and the pain and dysfunction diminished.

I would like to thank Dr. Raman for participating in this journalistic endeavor. His patients appreciate his care in relieving their pain and dysfunction.

Dr. Gelb

The physiologic neuromuscular dental paradigm puts a premium on the muscular and reduces the significance of the TMJ, articular disk and airway. The TMJ is objectively measured with MRI and cone beam CT and the airway with a polysomnogram and home sleep testing. The physiology of the airway affects the growth and development of the face and with it the mandible and TMJ.

Dr. Raman states, “Occlusal disharmony can result in hyperactivity and a disturbed pattern of muscle contractions, leading to muscular pain and joint overload.” AC looks at airway first, TMJ and myofascial second and occlusion third. Occlusal disharmony is not the driver in AC TMJ philosophy.

When considering the actual interdigitation of the teeth, it is not “the effort” needed by the muscles to bring the teeth into occlusion that is crucial, but more important, the efforts of the individual to breathe and maintain an open airway that affects the autonomic nervous system, oxidative stress and systemic inflammation.

47. Thomas NR. The Effect of Fatigue and TENS on the EMG Mean
2000.
66. Fricton questions the reliability and validity of neuromuscular dentistry bioinstrumentation. That sounds like the oft-repeated canard about “specificity and sensitivity” of these instruments in diagnosing TMD, as though it were a simple condition that could be addressed with a binary answer. With 66 markers of this syndrome, including intramural signs, headache, neck pain, ear pain, etc., the mathematical possibility of presentations is 2^66 = over 73 quintillion; ergo the improbable of randomized controlled trials. Both instruments measure parameters accurately. The FDA cleared them in 1994 and the ADA accepted them in 1996 because “these products were found to meet the Council’s Guidelines for Instruments as Aids in the Diagnosis of Temporomandibular Disorders.”

Dr. Raman’s Response to Critiques

I agree with Dr. Fricton that there is no “one-size-fits-all” approach to TMD. He states that the three authors besides him “rely on the same general treatment approach — that of primarily correcting the mandibular jaw position through splints.” The more one knows, the more one understands the nuances. However, only dentists have the necessary skills to correct mandibular position, which has an enormous impact on the whole body.

Dr. Fricton questions the reliability and validity of neuromuscular dentistry bioinstrumentation. That sounds like the oft-repeated canard about “specificity and sensitivity” of these instruments in diagnosing TMD, as though it were a simple condition that could be addressed with a binary answer. With 66 markers of this syndrome, including intramural signs, headache, neck pain, ear pain, etc., the mathematical possibility of presentations is $2^{66} = \text{over } 73 \text{ quintillion}; \text{ ergo the improbable of randomized controlled trials. Both instruments measure parameters accurately.}$ The FDA cleared them in 1994 and the ADA accepted them in 1996 because “these products were found to meet the Council’s Guidelines for Instruments as Aids in the Diagnosis of Temporomandibular Disorders.”

Electromyography (EMG) is a widely used medical diagnostic test. Why is it less valid than digital palpations?

Dr. Gelb appears unaware that physiological neuromuscular dentistry (PNMD) has progressed exponentially on the foundation laid by Dr. Jankelson. The PNMD approach includes achieving unstrained masticatory and cervical musculature, decompressed TMJs and improved airway. The resultant position of the TMJ in the example case demonstrates this point. Doppler and electrosonography were used in the diagnosis of this case but were not included above due to space constraints. Age 49 is not too old to move the teeth to permanently support an optimal jaw/neck position. The patient made an informed choice.

Dr. Simmons raises several good points. EMG provides information that an astute clinician uses along with other data for diagnosis and treatment. While many studies support this, more importance are the complex cases that were resolved. Palpation is used to augment objective data, not to take its place. He states that “muscles are the alarm” and “neuromuscular dentistry seems to be treating the secondary, not the primary cause of a patient’s pain and dysfunction.” PNMD treatment consists of...

License Needed to Play Movies in Your Practice

TDIC Risk Management Staff

If you are showing “The Lego Movie,” “Frozen,” “The Sound of Music” or any other movie in your practice, copyright is a consideration.

The Dentists Insurance Company reminds dentists that motion pictures and other programs available for rental or purchase are protected by the U.S. Copyright Act and are intended for personal, private or home use only. Movie presentations outside of the home, such as within a dental office, require a public performance license. TDIC reports increased calls and questions from dentists in several states about this license or about a letter the practice received regarding this topic.

The Motion Picture Licensing Corporation (MPLC) handles public performance licensing of more than 250,000 facilities across the nation, including thousands of dental offices. Sal Laudicina, president of the licensing division at MPLC, said some dentists still do not realize they need a license to show movies in their offices. However, this perception is changing through agreements with dental organizations and increased education.

MPLC offers a “blanket” or “umbrella” license that makes it simple to comply with federal copyright law regarding the public performance of audiovisual works, Laudicina said. “We represent Disney, Warner Brothers and more than 400 other motion picture producers, and the license applies to DVD or any other legal digital format whether streamed or downloaded.” The annual license fee is $330 per location, and MPLC offers a discount for offices with multiple locations.

The California Dental Association’s Legal Reference Guide states that dentists need to obtain a public performance license to show movies anywhere in the dental practice, including waiting and exam rooms. The legal guide also includes information about copyright violation penalties: “It is important to comply with the copyright law because infringement carries significant penalties. For example, if an infringement is considered ‘willful,’ you could be subject to statutory damages as high as $150,000 for each infringed work. Moreover, even if the
infringement is considered inadvertent, you could be subject to statutory damages ranging from $750 to $30,000 for each infringed work. You may also be subject to other costs, including reasonable attorneys’ fees to the prevailing party.”

Compared to potential noncompliance fees, the public performance license is notably less expensive.

MPLC has about 10,000 independent field representatives nationwide who send information to the corporation about businesses showing movies without a license, according to Laudicina.

If a violation is discovered, MPLC contacts the business via phone or letter and explains what needs to be done to stop copyright infringement. “We just say, ‘Here’s what you need to do,’ and we send an application for the license,” Laudicina said. “People want to do the right thing, and we make it easy for them to comply.”

Laudicina added that some dentists mistakenly think a letter about a public performance license is a scam. “Don’t ignore a letter about a public performance license,” he said. “If a letter is ignored, the violation becomes more egregious and that’s not a good thing. Take the time to check it out.”

TDIC’s Risk Management Advice Line answers questions about copyright compliance and other dental practice issues at 800.733.0634 Monday through Friday 7:30 a.m. to 5 p.m. PT.
SELL YOUR PRACTICE . . . .

. . . . to the right buyer!

Knowing how, means doing all of the following - with precision:

1. Valid practice appraisal.
2. Contract preparation and negotiations, including critical tax allocation consideration.
3. Bank financing or Seller financing, with proper agreements to adequately protect the Seller and make the deal close - realistically and expeditiously.
4. Performance of “due diligence” requirements, to prevent later problems.
5. Preparation of all documentation for stock sale, when applicable.

Lee Skarin & Associates has scores of Buyers in their database. The Buyers’ profiles personal desires and financial ability have been categorized to expertly select the right Buyer for your practice. Expert Buyer selection solidifies a deal. Lee Skarin & Associates services all of Southern California.

All six of these services costs no more. Maybe even less!

Lee Skarin & Associates is California’s leading Dental Practice Broker. Their in-house attorney, Kurt Skarin, PhD., J.D., specializes in these matters. He does all of the above, and more. He is the catalytic agent that makes the sale happen - quickly and smoothly.

Your calls are invited. Put our thirty years of experience to work for you!

YORBA LINDA: General Dentistry, 5 Ops, laser, Intra-oral camera, and digital X-rays. 3 hygiene and 3 doctor days/wk. #CAM531 – In Escrow
Dental Practice Act Compliance Q&A

CDA Practice Support

Following are answers to questions asked in recent months by dental practices. A Guide to Dental Practice Act Compliance is available on cda.org/practicesupport.

A new patient has been trying to obtain a copy of his radiographs from another dental practice. The other practice is asking the patient to pay $50 for the copy because the patient took advantage of an offer for free X-rays. Can the practice do that?

No. A dental practice may not charge a patient more than what state or HIPAA laws allow for copies of the patient record, even if the practice provided X-rays at no cost to the patient. Practices that offer free X-rays as a new patient incentive should be aware that denying a patient access to his or her records may lead the patient to file complaints with the Dental Board and the U.S. Department of Health and Human Services, which enforces HIPAA.

Allowable charges are:

- **Paper copy**: No more than 25 cents per page or 50 cents per page for copies made from microfilm. All reasonable costs, not exceeding actual costs, incurred by the dental office to provide the copies may be charged to the patient. This includes the cost of copying X-rays and postage if the patient requests receipt by mail.

- **Electronic copy**: The fee may not exceed the actual labor and material costs of fulfilling the request. If the practice maintains patient treatment records electronically and the patient requests an electronic copy, the practice must provide a copy in an electronic format agreed upon by both the patient and the practice. Labor cost may not include day-to-day maintenance of the records system. Many practices forgo charging a fee if they transmit the records directly to another dentist.

A new patient only wants a cleaning and does not want an exam and radiographs. What can we tell the patient?

Many patients are unfamiliar with the standards of dental practice. Simply inform the patient that “cleaning” is a generic term for “prophylaxis,” a term describing a dental treatment, and that treatment can only be provided after a dentist has examined the patient’s oral health and determined that treatment is necessary.

An RDA holds a specialty certificate. Is the RDA required to obtain 25 continuing education credits for each license and certificate (50 credits), or are 25 credits sufficient for renewal of both license and certificate?

The total number of C.E. units required for an individual with dual dental licenses and/or permits is the greatest number required for one license/permit. In this example, the RDA need only complete 25 units to renew both the license and specialty certificate.

CA Representative for the National Associaion of Practice Brokers (NAPB)

Can a dental practice offer an incentive to patients or staff to refer new patients to the practice?

Not in most situations. Providing an inducement or reward for a referral of a new patient can be a violation of Business & Professions Code 650(a), which states:

Except as provided in Chapter 2.3 (commencing with Section1400) of Division 2 of the Health and Safety Code, the offer, delivery, receipt, or acceptance by any person licensed under this division or the Chiropractic Initiative Act of any rebate, refund, commission, preference, patronage dividend, discount, or other consideration, whether in the form of money or otherwise, as compensation or inducement for referring patients, clients, or customers to any person, irrespective of any membership, proprietary interest, or coownership in or with any person to whom these patients, clients, or customers are referred is unlawful (leginfo.ca.gov/cgi-bin/displaycode?section=bpc&group=00001-01000&file=650-657). Practices that choose to reward staff with a bonus system should not base it on patient referrals. For patients who make referrals, a sincere thank-you note is recommended. Practice management consultants, some of whom recommend incentive programs for new patient referrals, need to be aware of the limitations placed on such programs by the Dental Practice Act.

Regulatory Compliance appears monthly and features resources about laws and regulations that impact dental practices. Visit cda.org/practicesupport for more than 600 practice support resources, including practice management, employment practices, dental benefit plans and regulatory compliance.
WHAT CLIENTS ARE SAYING:

“Dr. Bette Robin, Select Practice Services, Inc, sold my practice for the listed price, in record time. She brought only qualified buyers to my practice, buyers who shared my values and who would likely take excellent care of my patients and staff. Dr. Robin has the unique background of having been a highly successful dentist, as well as an attorney so she really understood my concerns and my practice. She was very ethical and kept me informed every step of the way. I highly recommend Dr. Robin.”

Carol Summerhays, D.D.S.,
San Diego Dentist

“When it comes to selling a dental practice, it doesn’t get any better than Dr. Bette Robin. Her expertise and experience got my practice sold for the full price, quickly and without any complications. The best part is that after the practice was sold there was a comfort in knowing that all parties were happy and there were no unexpected surprises. Since Dr. Robin is a lawyer as well as a Dentist, she was able to understand and write legally exactly what I wanted. I can’t thank her enough for making my transition special.”

Victor Feld D.D.S.
Irvine Dentist, Retired!!

ASK THE BROKER

Why isn’t there an MLS type service for dental practices like there is for home sales? It seems
like I need to contact every broker to find all the practices that are for sale.

Believe me, I felt the same way when I was a young dentist. I
even thought I might be able to change that when I started
brokering practices. However, now that I have been doing
practice transitions for 15 years, I understand why the system
will probably not change. It is a specialized niche market and too
small to be able to duplicate what can be done in large real estate
markets. Without boring you with a detailed explanation of the
intricacies of the dental brokerage business, let’s just say that
there is a lot more time and expense behind the scenes to bring a
practice to the market and feel confident that the practice is fully
exposed to all possible buyers.

So what does this mean for buyers? Since there is no “MLS”

system in place for dental practices, buyers need to contact every
active dental practice broker in their local area. Having no

“MLS” system in place is also part of the reason that the brokers
are routinely agents of the seller only, as the seller chooses the
broker that is responsible to do the “heaving lifting” of obtaining
all the necessary reports and documents to evaluate the practice.
While a good broker may spend the majority of their time in a
transition guiding buyers and facilitating steps that buyers need to
accomplish, brokers are almost always the agent of the seller.
Therefore, buyers need to understand that they will eventually
need to lean on their own accountant, attorney or practice
consultant to help guide them through the process.

In addition, Sellers need to understand that it IS important to
choose wisely when they hire a broker. There may be a big
difference between brokers when it comes to experience and their
credentials. Just as in dentistry, one usually gets what they pay
for. An experienced broker is much like an experienced dentist.
We don’t really know when we start a process whether it will go
smoothly or have a complication or two along the way. The
economic and legal landscape is always changing and a broker
with experience should be able to navigate those changes more
effectively. It is not as easy as one might think to change brokers
once the practice has been exposed to the market, so it is
normally not a good idea to try the discounted route first,
thinking you can simply change if it doesn’t work out. It also just
makes sense that more exposure should translate into more
buyers, which could translate into either a better price, a better fit
for the practice, or both!

Timothy G. Giroux, DDS is currently the Owner & Broker at Western Practice
Sales and a member of the nationally recognized dental organization, ADS Transitions.

Offering well-est. practice and 20 year old, 3,500 sq. ft. professional building. Office space is 1,755 sq. feet with 6 fully-equipped ops. New laser, and Dexis digital x-ray, digital camera, intra oral camera, and panorex. Approx. 1,200 active pts. and 3.5 doctor days/week. Call for details.

UPCOMING:
SAN JOSE GP
O’Connor Hospital area. Modern, well appointed office in 1,800 sq ft. 5 ops, 4 fully equipped. 4 day doctor work week. Grossing over $1M.
IMPLANTS

Titanium sensitivity

Purpose: The goal of this study was to systematically search the literature for the answer to the question “Is titanium sensitivity associated with allergic reactions in patients who have dental implants?”

Method: The focus question addressed was stated above in the purpose. The usual selection protocol was followed, including original articles, clinical and experimental studies, reference lists of potentially relevant original and review articles, intervention studies and articles published only in English. The authors searched electronic databases and hand searched the reference lists of original and review articles. Their initial efforts yielded 17 articles that were cut to seven relevant articles. Because of the limited number of original studies investigating allergic reactions in patients with titanium dental implants, the result of the review was changed to mainly summarize the relevant data.

Results: Six of the seven studies reported the duration of Ti implants in situ: one week to two years. Four of the studies showed the development of dermal inflammatory conditions, one study noted gingival hyperplasia and a case report described swelling in submental and labial sulcus and soft tissue hyperemia. Two of the included studies showed no allergic reaction. Metal hypersensitivity was detected using lymphocyte transformation testing and memory lymphocyte immunostimulation. Epicutaneous patch tests were performed in two studies and histological assessment of biopsy tissue obtained from inflamed peri-implant tissue was done in three studies.

Conclusion: Because titanium alloys are commonly used in implant dentistry due to their higher strength, the presence of alloy metals cannot be ruled out as the cause of the allergic reactions reported in these papers. Therefore, whether it is the titanium or other metals as alloys or contaminants in the implants that caused the reactions is unproven.

Clinical relevance: As is often the case in fundamental clinical questions, this systematic review yielded too few results to allow for a direct positive or negative conclusion to the question. However, the presence of several studies that show metal hypersensitivity related to titanium implant placement is of clinical significance and warrants our attention. This is not a trivial question; it is routinely asked by patients and it cannot be answered purely in the negative.

— David W. Richards, DDS, PhD
Image quality of different CBCT scanners

Clinical problem: Cone beam computed tomography (CBCT) is widely used in various aspects of everyday dental practice. Several CBCT scanners are commercially available and are tailored toward various applications. How could these scanners be evaluated and compared with each other?

Aim: To systematically and objectively evaluate the spatial and contrast resolution for various CBCT scanners at various clinically relevant settings.

Method: A customized phantom was constructed and rod patterns of various densities and line-pair grids were inserted into the phantom. Thirteen commercially available CBCT scanners and one multislice CT scanner were utilized to image the phantom under high- and low-resolution protocols utilizing various fields of view (FOV). Four observers scored the resultant images.

Results: There was a high intra-/inter-observer agreement for contrast and spatial resolution scoring. Image quality, as reflected by perceived contrast and spatial resolution, varied considerably among the various scanners and among the different imaging parameters utilizing the same scanner.

Conclusions: CBCT devices are generally suitable for imaging high-contrast structures at moderate spatial resolution. Certain exposure protocols improve visualization of lower contrast structures or fine details.

Bottom line: Different CBCT scanners produced images of varying spatial and contrast resolution. Optimization of exposure parameters is important to achieve diagnostic images while delivering as low as reasonably achievable (ALARA) radiation exposure to the patient.

**PHENOMENAL SAN FRANCISCO EAST BAY OPPORTUNITY**

2013 Produced $2.4 Million, Collected $2 Million & realized Profits of $1.1+ Million

Success here is contrary to basic tenet which is “build a strong Hygiene Department.” Such a theme maintains the patient foundation with each year yielding new patients each month with little competition. New patients are handled and immediately tending to their neglected oral health. This location is a “goldmine” guaranteeing a continuous high volume flow of another harvest as a result of renewed insurance benefits and watches that now need to be addressed. This practice believes that the “real opportunity” is how

**Notifyr** *(Arnoldus Wilhelmus Jacobus van Dijk, $3.99)*

Notifyr is a remarkable app for iOS that brings mobile device notifications to the Mac. Users already familiar with Notifications Center for the Mac will be impressed with its seamless integration. Users must install two applications: one for iOS available from the App Store and one for Mac available from the developer’s website. Users follow instructions to pair their iOS devices to their Macs via Bluetooth LE (low energy) when launching the app for the first time. The app must be continually running in the background in order to send notifications to the Mac. Anytime an iOS device is in range of its paired Mac, the app will send all notifications that appear on the iOS device to Notifications Center on the Mac. Notifications from any iOS app (e.g., Instagram, Snapchat, WhatsApp) are supported. The Mac application counterpart is a Preference Pane that allows a user to toggle notifications on or off from individual iOS applications, which is useful to eliminate repeat notifications from apps that both Mac and iOS share. Many users will find Notifyr to be easy to use and extremely useful. For Mac users with iOS devices, this app makes it simple to have one central location for viewing notifications across all devices.

— Hubert Chan, DDS

**UpTo** *(Rock City Apps, Free)*

This new calendar app for iOS and Android devices provides a unique way to combine personal and business events into one interactive spot. UpTo functions as a traditional calendar that also allows users to “follow” other people or organizations. Once those accounts are being followed, the user can add their events to his or her own calendar. The app has two layers. The front layer is the user’s existing calendar. The back layer, which can be accessed via a simple pinch of the screen, is the events from other calendars the user follows. If users find an event interesting, they can add it to their main calendar. These events include movie and music releases, upcoming concerts in their city and more. Users who belong to a club or group can also create a separate calendar for that group and then share it with other members. Push notifications are also a feature for events.

**Nest Protect** *(Nest Labs, $99)*

Nest Labs recently unveiled the latest addition to its offering of connected home devices with the debut of Nest Protect, its smoke and carbon monoxide detector. Two different models are offered — one for hard-wired thermostats and one that runs on regular batteries — and the installation requires only four screws. A few clicks of the Nest Protect itself painlessly syncs it to the Nest app on a user’s smartphone or tablet. Operationally, the Nest Protect is the height of minimalism; because it’s a smoke detector, it sits in the background and requires no interaction, other than the recommended regular testing to ensure it is functioning properly. According to Nest, the majority of U.S. home fire deaths occur in homes with no smoke detectors or, worse yet, smoke detectors that have had their batteries removed (presumably from the annoying low-battery warning we have all heard chirping late at night on our old smoke detectors). Nest wants to fix this with its Protect, which notifies users of low battery warnings via their smartphones.

— Blaine Wasylkiw, director of online services, CDA

**Instagram update** *(Instagram, Free)*

Those who wanted to be more artsy with their photos now have a chance, using the updated version of Instagram. Traditionally, users were only able to select from the 19 photo filters in the app (you know, amaro, mayfair, earlybird and the rest). But now, the filters are customizable, allowing more photo editing. Though no new filters were added, there is now an option to use a slider to determine how much of a filter to use. Users can also try new features such as brightness, contrast, warmth, saturation, highlights, shadows, vignette and sharpen, among others, to further edit their photos. These new features also operate using a slider function.

Would you like to write about new technology? Dentists interested in contributing to this section should contact Tech Trends Editor Blake Ellington at blake.ellington@cda.org.
What is the greatest scourge known to mankind today? No, it's not the common cold. We have given up on the common cold except as a source of revenue for manufacturers of sneezing, coughing, runny nose, fever and malaise medications. Long after even the cockroaches have departed this earth, the common cold will still be with us, defying nuclear holocaust, Armageddon, and black holes to eradicate it.

The scourge I refer to is snoring, the cause of more marital discord than indiscriminate channel changing or wrong-end-of-the-toothpaste-tube squeezing. Snoring has sold more twin beds and peopled more two-bedroom homes than has ever been recorded.

At night, I lie in my customary fetal position, blankie drawn up snugly about my ears, thinking about a terrific idea I have for a comic strip featuring an engineering nerd and his pet dog. The nerd’s loftiest ambition is to survive his mind-numbing life in a cubicle, while his dog is busy trying to take over the world by posing as a business consultant. I am considering the money-making possibilities of this when I receive a sharp poke between the shoulder blades.

“Stop snoring!” my helpmate demands.

“You’re snoring,” she insists. I deny even the possibility of this and return to my meditations only to receive, two minutes later, another blow,
considerably sharper than the first. This tableau has become a nocturnal ritual, leaving me with enough contusions to qualify for abused spouse protection.

I decided to do some research on snoring to buttress my position. Centuries ago, it seems, snoring was thought to be the result of demons within the skull trying to get out at night. To test the validity of this theory, snorers frequently had their skulls clove by dedicated researchers; and, sure enough, the snoring stopped as the demons escaped.

More recent studies have shown that snoring is the direct result of breathing; and scientists discovered that if you could stop a snorer from breathing long enough, the problem would disappear. Also disappearing is the stereotype of the typical snorer: a man (women do not snore as they do not sweat as they do not grow hair in their ears) lies flat on his back, mouth open, from which arises a line of little “sz” terminating in a balloon containing a log being cut by a saw. The descriptive words for this act look something like “snor-r-f,” “bla-a-ff” and sometimes “y-o-on-n-k.”

Meet the new breed of snorer. Contrary to the stereotype, I can demonstrate the ability to snore while lying on my side, mouth clenched shut while thinking that I am wide awake. If I apparently can’t distinguish between being awake or asleep, I may have a problem more serious than just snoring. Besides my sounding like an International Harvester during the height of the season, my bride claims that occasionally I go for long minutes without breathing at all, followed by an explosive snort to make up for lost time.

My research shows this to be a phenomenon known as sleep apnea that is considered by students of sleeping disorders to be a serious problem. Having always been the type of person who will face his problems whenever there appears to be no other way out, I have sent away for a device known as an oral proprioceptive stimulator. This is a plastic appliance to be worn in the palate at night and resembles a flipper without teeth, but with a movable flap at the distal of the soft palate that pushes the base of the tongue down while the wearer attempts to keep his dinner down.

The theory behind its operation is something I don’t have time to understand, nor the capacity to do so. I bought it as an antinusoring machine; and although the jury is still out, I think the portents are good. My wife says she thinks it may be working. She came in from the other room and woke me up to tell me this. I was pleased, as you can imagine I would be, to be awakened at 2 a.m. with this kind of information. As it turns out, being aroused periodically is not a bad idea if you wish to avoid one other nocturnal problem, that of drowning in your sleep. My salivary glands, which seem to be the last of my glands to show the ravages of time, are producing upwards of 50 gallons of saliva every night in a frantic effort to wash out the appliance before morning.

I think young people who are out toomcatting around all night, when they have the natural ability to sleep straight through from 10:30 p.m. until 9 a.m., would do well to listen to the laments of their elders who can never remember having had this blessing once. Grab as many zeds as you can while you’re young, kids, there will be plenty of time at night later to consider other pursuits like wondering if there is any Alka-Seltzer in the cabinet or trying to determine what time the luminous dial on the clock says without finding your glasses first.
